Important Natural Enemies of Sapota Insect Pests

Parasitoids

- Coccophagus cowperi
- Parasitic wasp
- Fopios arisanus
- Diachasmimorpha kraussi

Predators

- Cryptolaemus montrouzieri
- Hover fly
- Ladybird beetle
- Geocoris spp.
- Lacewing
- Big-eyed bug

Plants Suitable for Ecological Engineering in Sapota Orchard

- Lablab bean
- Cowpea
- Carrot
- Sunflower
- Buckwheat
- Alfalfa
- Maize
- Mustard
- French bean
- Marigold
- Coriander
- Chrysanthemum
The AESA based IPM – Sapota, was compiled by the NIPHM working group under the Chairmanship of Dr. Satyagopal Korlapati, IAS, DG, NIPHM, and guidance of Shri. Utpal Kumar Singh, IAS. JS (PP). The package was developed taking into account the advice of experts listed below on various occasions before finalization.

**NIPHM Working Group:**

**Chairman**: Dr. Satyagopal Korlapati, IAS, Director General  
**Vice-Chairmen**: Dr. S. N. Sushil, Plant Protection Advisor  
: Dr. P. Jeyakumar, Director (PHM)

**Core Members:**
1. Er. G. Shankar, Joint Director (PHE), Pesticide Application Techniques Expertise.  
2. Dr. O. P. Sharma, Joint Director (A & AM), Agronomy Expertise.  
3. Dr. Dhana Raj Boina, Assistant Director (PHM), Entomology Expertise.  
4. Dr. Satish Kumar Sain, Assistant Director (PHM), Pathology Expertise.  
5. Dr. M. Narsi Reddy Assistant Scientific Officer (PHM), Entomology Expertise.

**Contributions by DPPQ&S Experts:**
1. Shri Ram Asre, Additional Plant Protection Advisor (IPM)  
2. Shri R. Murali, Deputy Director (Entomology Expertise)  
3. Dr. Sanjay Arya, Deputy Director (Plant Pathology)  
4. Dr. Subhash Kumar, Deputy Director (Weed Science)

**Contributions by External Experts:**
1. The Director, Indian Institute of Horticultural Research, Hessaraghatta lake Post Bangalore-560089  
2. Dr. V. K. Kalra, HOD (Entomology), CCS Haryana Agricultural University, Hisar- 125004, Haryana  
3. Director of Research, CSK, Himachal Pradesh Krishi, Vishvavidyalaya, Palampur.  
4. Director of Research, Dr. Balasaheb Sawant Konkan Krishi Vidyapeeth, Dapoli-415712,Dist-Ratnagiri.  
5. Directorate of Experiment Station, G. B. Pant University of Agriculture & Technology Pantnagar-263145, Dist. Udham singh Nagar (Uttarakhand, India)  
6. Dr. S. K. Panda, Professor & Head, Department of Entamology, College of Agriculture, Odhisha University of Agriculture & Technology, Bhubaneswar-751003  
7. Dr. K. C. Sahu, Professor & Head, Department of Plant pathology, College of Agriculture, Odhisha University of Agriculture & Technology, Bhubaneswar-751003  
8. Dr. S.N. Mohapatra, Professor & Head, Department of Nematology, College of Agriculture, Odhisha University of Agriculture & Technology, Bhubaneswar-751003  
9. Dr. Jayalaxmi Ganguli, Asst. Professor (Entomology), IGKV, Raipur (CG) 492 012  
10. Dr. Narendra Lakpale, Asst. Professor, (Plant Pathology), IGKV, Raipur (CG) 492 012.

FOREWORD

Intensive agricultural practices relying heavily on chemical pesticides are a major cause of widespread ecological imbalances resulting in serious problems of insecticide resistance, pest resurgence and pesticide residues. There is a growing awareness world over on the need for promoting environmentally sustainable agriculture practices.

Integrated Pest Management (IPM) is a globally accepted strategy for promoting sustainable agriculture. During last century, IPM relied substantially on economic threshold level and chemical pesticides driven approaches. However, since the late 1990s there is a conscious shift to more ecologically sustainable Agro-Eco System Analysis (AESA) based IPM strategies. The AESA based IPM focuses on the relationship among various components of an agro-ecosystem with special focus on pest-defender dynamics, innate abilities of plant to compensate for the damages caused by the pests and the influence of abiotic factors on pest buildup. In addition, Ecological Engineering for pest management - a new paradigm to enhance the natural enemies of pests in an agro-ecosystem is being considered as an important strategy. The ecological approach stresses the need for relying on bio intensive strategies prior to use of chemical pesticides.

Sincere efforts have been made by resource personnel to incorporate ecologically based principles and field proven technologies for guidance of the extension officers to educate, motivate and guide the growers to adopt AESA based IPM strategies, which are environmentally sustainable. I hope that the AESA based IPM packages will be relied upon by various stakeholders relating to Central and State government functionaries involved in extension and Scientists of SAUs and ICAR institutions in their endeavour to promote environmentally sustainable agriculture practices.

Date: 6.3.2014

(Avinash K. Srivastava)
FOREWORD

IPM as a holistic approach of crop protection based on the integration of multiple strategies viz., cultural, physical, mechanical, biological, botanical and chemical. Over the years IPM underwent several changes, shifting its focus from damage boundary, economic injury to economic threshold. Currently most stakeholders rely upon economic threshold levels (ETL) and tend to apply chemical pesticides at the first instance in the event of a pest attack, through Government of India has advocated need based and judicious application of chemicals. This approach is likely to cause adverse effects on agro-ecosystems and increase the cost of agricultural production due to problems of pest resurgence, insecticide resistance and sustainability.

During the late 90s FAO started advocating Agro-Ecosystem Analysis (AESA) based IPM. Experience in different countries have since show that AESA, which takes into account ecological principles and relies on the balance that is maintained by biotic factors in an ecosystem has also resulted in reduction in cost of production and increase in yields. AESA based IPM also takes into account the need for active participation of farmers and promotes experiential learning and discovery based decision making by farmers. AESA based IPM in conjunction with ecological engineering for pest management promotes bio-intensive strategies as against current chemical intensive approaches, while retaining the option to apply chemical pesticides judiciously as a measure of last resort.

The resource persons of NIPHM and DPPQ&S have made sincere efforts in revising IPM packages for different crops by incorporating agro-ecosystem analysis, ecological engineering, pesticide application techniques and other IPM options with the active cooperation of crop based plant protection scientists working in state Agricultural Universities and ICAR institutions. I hope this IPM package will serve as a ready reference for extension functionaries of Central / State Governments, NGOs and progressive farmers in adopting sustainable plant protection strategies by minimizing the dependence on chemical pesticides.

(Utpal Kumar Singh)
PREFACE

Need for environmentally sustainable agricultural practices is recognised worldwide in view of the wide spread ecological imbalances caused by highly intensive agricultural systems. In order to address the adverse impacts of chemical pesticides on agro-ecosystems, Integrated Pest Management has evolved further from ETL based approach to Agro-ecosystem Analysis based Integrated Pest Management (IPM).

In AESA based IPM the whole agro-ecosystem, plant health at different stages, built-in-compensation abilities of the plant, pest and defender population dynamics, soil conditions, climatic factors and farmers’ past experience are considered. In AESA, informed decisions are taken by farmers after field observation, AESA chart preparation followed by group discussion and decision making. Insect zoo is created to enable the farmer understand predation of pests by Natural Enemies. AESA based PHM also results in reduction of chemical pesticide usage and conserves the agro-ecosystems.

Ecological Engineering for Pest Management, a new paradigm, is gaining acceptance as a strategy for promoting Biointensive Integrated Pest Management. Ecological Engineering for Pest Management relies on cultural practices to effect habitat manipulation and enhance biological control. The strategies focus on pest management both below ground and above ground. There is growing need to integrate AESA based IPM and principles of ecological engineering for pest management.

There is a rising public concern about the potential adverse effects of chemical pesticides on the human health, environment and biodiversity. The intensity of these negative externalities, through cannot be eliminated altogether, can be minimized through development, dissemination and promotion of sustainable biointensive approaches.

Directorate of Plant Protection Quarantine and Storage (DPPQ&S), has developed IPM package of practices during 2001 and 2002. These packages are currently providing guidance to the Extension Officers in transferring IPM strategies to farmers. These IPM package of practices, have been revised incorporating the principles of AESA based IPM in detail and also the concept of Ecological Engineering for Pest Management. It is hoped that the suggested practices, which aim at enhancing biodiversity, biointensive strategies for pest management and promotion of plant health, will enable the farmers to take informed decisions based on experiential learning and it will also result in use of chemical pesticides only as a last resort & in a safe and judicious manner.
AESA BASED IPM PACKAGE FOR SAPOTA

Sapota-Plant description:

Sapota [Manilkara zapota (L.) Royen; Family: Sapotaceae] commonly known as the sapodilla, is a long-lived, evergreen tree native to southern Mexico, Central America and the Caribbean. Sapodilla can grow to more than 30 m tall with an average trunk diameter of 1.5 m. The average height of cultivated specimens, however, is usually between 9 and 15 m with a trunk diameter not exceeding 50 cm. It is wind-resistant and the bark is rich in a white, gummy latex called chicle. The ornamental leaves are medium green and glossy. They are alternate, elliptic to ovate, 7–15 cm long, with an entire margin. The white flowers are inconspicuous and bell-like, with a six-lobed corolla. An unripe fruit has a firm outer skin and when picked, releases white chicle from its stem. A fully ripened fruit has saggy skin and does not release chicle when picked. The fruit is a large ellipsoid berry, normally 4–8 but up to 15 cm in diameter, containing two to five seeds. Inside, its flesh ranges from a pale yellow to an earthy brown color with a grainy texture akin to that of a well-ripened pear. The seeds are black and resemble beans, with a hook at one end that can catch in the throat if swallowed.

I. PESTS

A. Pests of National Significance:

1. Insect pests
   1.1 Leaf webber: Nephopteryx eugraphella Ragonot (Lepidoptera : Pyralidae)
   1.2 Green scale: Coccus viridis Green (Hemiptera: Coccidae)
   1.3 Fruit fly: Bactrocera dorsalis (Hendel), B. zonata (Saunders) (Tephritidae: Diptera)
   1.4 Bud borer: Anarsia achrasella Latreille (Lepidoptera: Gelechiidae)
   1.5 Sapota seed borer: Trymalitis margarias Meyrick (Lepidoptera: Tortricidae)
   1.6 Budworm: Anarsia epotias Meyrick (Lepidoptera: Gelechiidae)
   1.7 Stem borer: Plocaederus ferrugineus L. (Coleoptera: Cerambycidae)
   1.8 Hairy caterpillar: Metanastria hystaca Cramer (Lepidoptera: Lasiocampidae)
   1.9 Leaf miner: Acrocercops syngamma (Meyrick) (Lepidoptera: Gracillaridae)
   1.10 Spiraling whitefly: Aleurodicus dispersus Russell (Hemiptera: Aleyrodidae)
   1.11 Leaf twisting weevil: Apoderus tranquebaricus Fabricius (Coleoptera: Curculionidae:)
   1.12 Scale: Chloropulvinaria psidii (Maskell) (Hemiptera: Diaspididae)
2. Diseases
   2.1 Leaf spot: *Phaeophleospora indica* Chinnappa
   2.2 Leaf blight: *Fusicoccum sapoticola* Chinnappa & V.G. Rao
   2.3 Sooty mould: *Capnodium* sp.
   2.4 Postharvest diseases
      2.4.1 Soft rot: *Pestalotiopsis mangiferae* (Henn.) Steyaert
      2.4.2 Fruit rot: *P. palmivora, Versicolar sapotae*
   2.5 Basal rot: *Ceratocystis paradoxa* (Dade) C. Moreau
   2.6 Heart rot: *Phytophthora parasitica* Dastur
   2.7 Anthracnose: *Colletotrichum gleosporioides* (Penz.) Penz. & Sacc

3. Weeds
   Broadleaf
   3.1 Tick weed: *Cleome viscosa* L. (Capparidaceae)
   3.2 Coat buttons: *Tridax procumbens* L. (Fabaceae)
   3.3 Congress grass: *Parthenium hysterophorus* L. (Asteraceae)
   3.4 Horse Purslane: *Trainthema portulacastrum* L. (Aizoeaceae)
   3.5 Croton weed: *Eupatorium odoratum* L. (Asteraceae)
   3.6 Siam weed: *Chromolaena odorata* L. R.M. King & H. Rob (Asteraceae)
   3.7 False amaranth: *Digera arvensis* L. (Amaranthaceae)
   3.8 Spurge: *Euphorbia hirta* L. (Euphorbiaceae)
   Grasses
   3.9 Crab grass: *Digiteria sanguinalis* (L.) Scop. (Poaceae)
   3.10 Yellow foxtail: *Setaria glauca* (L.) P. Beauv. (Poaceae)
   3.11 Bermuda grass: *Cynodon dactylon* (L.) Pers. (Poaceae)
   3.12 Torpedo grass: *Panicum repens* L. (Poaceae)
   Sedges
   3.13 Purple nutsedge: *Cyperus rotundus* L. (Cyperaceae)
   3.14 Flat sedge: *Cyperus iria* L. (Cyperaceae)

B. Pests of Regional Significance
   1. Insect pest
      1.1 Mealybug: *Rastrococcus iceryoides* Green (Hemiptera: Pseudococcidae)
   2. Diseases
      2.1 Faciation: *Botrydiplodia theobromae* Pat.
      2.2 Phanerogamic parasites
II. AGRO-ECOSYSTEM ANALYSIS (AESA) BASED INTEGRATED PEST MANAGEMENT (IPM)

A. AESA:
The IPM has been evolving over the decades to address the deleterious impacts of synthetic chemical pesticides on environment ultimately affecting the interests of the growers. The economic threshold level (ETL) was the basis for several decades but in modern IPM (FAO 2002) emphasis is given to AESA where growers take decisions based on larger range of orchard observations. The health of a plant is determined by its environment which includes physical factors (i.e. soil, rain, sunshine hours, wind etc.) and biological factors (i.e. pests, diseases and weeds). All these factors can play a role in the balance which exists between herbivore insects and their natural enemies. Understanding the intricate interactions in an ecosystem can play a critical role in pest management.

Decision making in pest management requires a thorough analysis of the agro-ecosystem. Grower has to learn how to observe the crop, how to analyze the field situation and how to make proper decisions for their crop management. This process is called the AESA. Participants of AESA will have to make a drawing on a large piece of paper (60 x 80 cm), to include all their observations. The advantage of using a drawing is that it requires the participants/growers to observe closely and intensively. It is a focal point for the analysis and for the discussions that follow, and the drawing can be kept as a record.

AESA is an approach, which can be gainfully employed by extension functionaries and growers to analyze the field situations with regards to pests, defenders, soil conditions, plant health and the influence of climatic factors and their relationship for growing a healthy crop. The basic components of AESA are:

- Plant health at different stages
- Built-in compensation abilities of plants
- Pest and defender population dynamics
- Soil conditions
- Climatic factors
- Growers past experience

Principles of AESA based IPM:

Grow a healthy crop:

- Select a variety resistant/tolerant to major pests
- Select healthy seeds/seedlings/planting material
- Treat the seeds/seedlings/planting materials with recommended pesticides especially biopesticides
- Follow proper spacing
- Soil health improvement (mulching and green manuring whenever applicable)
- Nutrient management especially by using organic manures and biofertilizers based on the soil test results. If the dose of nitrogenous fertilizers is too high the crop becomes too succulent and therefore susceptible to insects and diseases. If the dose is too low, the crop growth is retarded. So, the growers should apply an appropriate amount of nutrients for best results.
- Proper irrigation

Observe the orchard regularly (climatic factors, soil and biotic factors):

Growers should:

- Monitor the field situation of the orchard at least once a week (soil, water, plants, pests, natural enemies, weather factors etc.)
- Make decisions based on the field situations of the orchard and Pest: Defender ratio (P: D ratio)
- Take direct action when needed (e.g. collect egg masses, remove infested plants etc.)
Plant compensation ability:
Compensation is defined as the replacement of plant biomass lost to herbivores and has been associated with increased photosynthetic rates and mobilization of stored resources from source organs to sinks (e.g., from roots and remaining leaves to new leaves) during active vegetative growth period. Plant tolerance to herbivory can arise from the interaction of a variety of plant traits and external environmental factors. The ability of the plant to compensate for the reduced acquisition of resources by the production of new organs or by remobilization of reserves may also mitigate biotic stress effects.

Understand and conserve defenders:
- Know defenders/natural enemies to understand their role through regular observations of the agro-ecosystem
- Avoid the use of chemical pesticides especially with broad-spectrum activity

Insect zoo:
In orchard various types of insects are present. Some are beneficial and some may be harmful. Generally growers are not aware about it. Predators (friends of the growers) which feed on pests are not easy to observe in orchard. Insect zoo concept can be helpful to enhance growers’ skill to identify beneficial and harmful insects. In this method, unfamiliar/unknown insects are collected in plastic containers with brush from the orchard and brought to a place for study. Each insect is placed inside a plastic bottle together with parts of the plant and some known insect pests. Insects in the bottle are observed for certain time and determined whether the test insect is a pest (feeds on plant) or a predator (feeds on other insects).

Pest: Defender ratio (P: D ratio):
Identifying the number of pests and beneficial insects helps the growers to make appropriate pest management decisions. Sweep net, visual counts etc. can be adopted to arrive at the numbers of pests and defenders. The P: D ratio can vary depending on the feeding potential of natural enemy as well as the type of pest. The natural enemies of sapota insect pests can be divided into 3 categories 1. parasitoids; 2. predators; and 3. pathogens.
Model Agro-Ecosystem Analysis Chart

Date:  
Village:  
Grower:  

Decision taken based on the analysis of orchard situations

Soil conditions  
Weather conditions  
Diseases types and severity  
Weeds types and intensity  
Rodent damage (if any)  
No. of insect pests  
No. of natural enemies  
P: D ratio  

The general rule to be adopted for management decisions relying on the P: D ratio is 2: 1. However, some of the parasitoids and predators will be able to control more than 2 pests. Wherever specific P: D ratios are not found, it is safer to adopt the 2: 1, as P: D ratio. Whenever the P: D ratio is found to be favourable, there is no need for adoption of other management strategies. In cases where the P: D ratio is found to be unfavourable, the farmers can be advised to resort to inundative release of parasitoids/predators depending upon the type of pest. In addition to inundative release of parasitoids and predators, the usage of microbial biopesticides and biochemical biopesticides such as insect growth regulators, botanicals etc. can be relied upon before resorting to synthetic chemical pesticides.

Decision making:

Growers become experts in crop management:

Growers have to make timely decisions about the management of their orchards. AESA growers have learned to make these decisions based on observations and analysis viz., abiotic and biotic factors of the crop ecosystem. The past experience of the growers should also be considered for decision making. However, as field conditions of orchard continue to change and new technologies become available, growers need to continue improving their skills and knowledge.

- Growers are capable of improving farming practices by experimentation
• Growers can share their knowledge with other growers

**AESA methodology:**

• Go to the orchard in groups (about 5 growers per group). Walk across the field and choose 20 trees/acre randomly. Observe keenly each of these trees and record observations:
  • Tree: 5-6 samples per tree (fruits/leaves/inflorescence/stem bark/roots/soil/insects, host plants) should be collected where, one sample from top, four samples from all the four sides (north, south, east, west) and one from bottom/soil, depending upon the requirement of study/observations and if necessary.
  • Insect pests: Observe and count insect pests at different places on the plant.
  • Defenders (natural enemies): Observe and count parasitoids and predators.
  • Diseases: Observe leaves and stems and identify any visible disease symptoms and severity.
  • Weeds: Observe weeds in the field and their intensity.
  • Water: Observe the water situation of the field.
  • Weather: Observe the weather condition.

• While walking in the orchard, manually collect insects in plastic bags. Use a sweep net to collect additional insects. Collect plant parts with disease symptoms.
• Find a shady place to sit as a group in a small circle for drawing and discussion.
• If needed, kill the insects with some chloroform (if available) on a piece of cotton.
• Each group will first identify the pests, defenders and diseases collected.
• Each group will then analyze the field situation of the orchard in detail and present their observations and analysis in a drawing (the AESA drawing).
• Each drawing will show a plant representing the field situation of the orchard. The weather conditions, water level, disease symptoms, etc. will be shown in the drawing. Insect pests will be drawn on one side. Defenders (beneficial insects) will be drawn on another side. Write the number next to each insect. Indicate the plant part where the pests and defenders were found. Try to show the interaction between pests and defenders.
• Each group will discuss the situation and make a crop management recommendation.
• The small groups then join each other and a member of each group will now present their analysis in front of all participants.
• The facilitator will facilitate the discussion by asking guiding questions and makes sure that all participants (also shy or illiterate persons) are actively involved in this process.
• Formulate a common conclusion. The whole group should support the decision on what field management of the orchard is required in the AESA plot.
• Make sure that the required activities (based on the decision) will be carried out.
• Keep the drawing for comparison purpose in the following weeks.

**Data recording:**

Growers should record data in a notebook and drawing on a chart:
• Keep records of what has happened help us making an analysis and draw conclusions

**Data to be recorded:**

• **Tree situations (e.g. for AESA):** Plant health; pests, diseases, weeds; natural enemies; soil conditions; irrigation; weather conditions
• **Input costs:** Seeds; fertilizer; pesticides; labour
• **Harvest:** Yield (Kg/acre); price of produce (Rs./Kg)

**Some questions that can be used during the discussion:**

• Summarize the present situation of the orchard.
• What crop management aspect is most important at this moment?
• Is there a big change in tree situation compared to last visit? What kind of change?
• Is there any serious pest or disease outbreak?
• What is the situation of the beneficial insects?
• Is there a balance in the field between pests and defenders?
• Were you able to identify all pests and diseases?
• Do you think the tree is healthy?
• What management practices are needed at this moment?
• When will it be done? Who will do it? Make sure that responsibilities for all activities are being discussed.
• Are you expecting any problems to emerge during the coming week such as congenial weather conditions for pest buildup?
• What are the problems? How can we avoid it? How can we be prepared?
• Summarize the actions to be taken.

Advantages of AESA over ETL:

One of the problems of the ETL is that it is based on parameters that are changing all the time, and that are often not known. The damage or losses caused by a certain density of insects cannot be predicted at all. In ETL the due recognition of the role of natural enemies in decreasing pest population is ignored. Growers cannot base their decisions on just a simple count of pests. They will have to consider many other aspects of the tree (tree ecology, growth stage, natural enemies, weather condition, etc.) and their own economic and social situation before they can make the right crop management decisions. In ETL based IPM, natural enemies, plant compensation ability and abiotic factors are not considered. In AESA based IPM emphasis is given to natural enemies, plant compensation ability, abiotic factors and P: D ratio.

AESA and farmer field school (FFS):

AESA is a season-long training activity that takes place in the Grower orchard. It is season-long so that it covers all the different developmental stages of the tree and their related management practices. The process is always learner-centered, participatory and relying on an experiential learning approach and therefore it has become an integral part of FFS.

Growers can learn from AESA:

• Identification of pests and their nature of damage
• Identification of natural enemies
• Management of pests
• Water and nutrient management
• Influence of weather factors on pest buildup
• Role of natural enemies in pest management

FFS to teach AESA based IPM skills:
**B. Field scouting:**
AESA requires skill, so only the trained growers can undertake this exercise. However, other growers also can do field scouting in their own orchard at regular intervals to monitor the major pest situation. Surveillance on pest occurrence at the main orchard should commence soon after tree establishment and at weekly intervals thereafter. In each tree, select five branches randomly for recording of insects as per procedure finalized for individual insects.

**Sampling in fruit crops:**
A person doing sampling is known as an inspector or scout. The fruit crops are perennial in nature and before starting the surveillance process an inspector or scout who is going to implement the activity should know about the nature of crop as well as different crop stages and its growth stages. Knowing crop and its nature helps in identifying the important pests and diseases because the pests and diseases infest and infect, respectively, certain stage or part of the plant.

**Sampling patterns:**
Different methods of sampling are reported and being utilized for sampling in crops as well as in fruit plants such as random, scattered etc. However, some of them are specific to the crop/disease/pests and growth stage (some of them are to be utilized at initial stage and/or for subsequent plant growth stage). Also the sampling methods may differ based on the nature and requirement of the study such as estimating disease incidence and/or disease severity. For a common orchard study, the assessment methods should not only be easy and quick in use for a wide range of conditions, but also adequately reliable, reproducible, and accurate/precise. However, this is not always possible. Generally, in fruit crops the following sampling patterns are used:

- **Zig-zag pattern.** Sampling a fallow orchard or one with no obvious symptoms in the current crop to see the incidence as well as sampling of viral, wilt disease.
- **Circle pattern.** Sampling within the drip line of trees and shrubs and for powdery mildew, downy mildew and leaf spot diseases etc.
- **Star pattern.** Sampling from a damaged area.

**Sampling frequency:**
Sampling frequency or interval depends on pest generation interval or number of generations per year, potential for population increase between generations, stage of crop- pathogen infection etc. Generally, if initial survey is already implemented and some results are with the surveillance manager, then based upon the results of pest/disease incidence/intensity and weather parameters, the surveillance frequency/interval is decided to get comprehensive view of the pests and diseases development/population dynamics as well as biocontrol agent’s population (if present in the crop ecosystem). In subsequent survey, monitoring for the pest, pathogen, and biocontrol agent must be carried out to get the following detailed information:
• Relative pest measuring estimates: Counting the representative samples in a given area.
• Absolute pest measuring estimates: Counting all individuals in a population in a given area which determine total pest population size in a given area. It is very effective pest surveillance research tool but very time consuming, therefore, not practical and/or not economically feasible.
• Get an idea of number of pests per unit: To estimate pests per plant and/or area to make the decision.
• Get an idea of weather at the site: In addition to the pest estimation, the prevailing weather conditions, which may affect pest development and/or population buildup, are observed and recorded.
• Get an idea of biocontrol agents: To strengthen the management strategies, biocontrol agent population size, if available, in a given area is to be determined.

**For insect pests:**

**Fruit fly:** Population should be counted on three leaves (top and middle portion) of new shoot at 5 sites randomly in each tree.

**For Diseases:**

Whenever scouting, be aware that symptoms of plant disease problems may be caused by any biotic factors such as fungal, bacterial, viral pathogens or abiotic factors such as weather, fertilizers, nutrient deficiencies, pesticides and abiotic soil problems. In many cases, the cause of the symptom is not obvious. Close examination, and laboratory culture and analysis are required for proper diagnosis of the causal agent of disease. Generally fungal diseases cause the obvious symptoms with irregular growth, pattern & colour (except viruses), however abiotic problems cause regular, uniform symptoms. Pathogen presence (signs) on the symptoms can also be observed like fungal growth, bacterial ooze etc. Specific and characteristic symptoms of the important plant diseases are given in description of diseases section.

**Root sampling:** Always check plants that appear unhealthy. If there are no obvious symptoms on plants, examine plants randomly and look for lesions or rots on roots and stems. Observe the signs of the causal organism (fungal growth or ooze). Always check plants that appear unhealthy. It is often necessary to wash the roots with water to examine them properly. If the roots are well developed, cut into them to examine the roots for internal infections (discolouration & signs). Count the total number of pseudostem damaged/infested/infected due to rot should be counted and incidence should be recorded.

**Leaf sampling:** Examine all leaves and or sheaths on each plant for lesions and determine the amount area of leaf infection. Leaf diseases cause most damage during the seedling and flowering stages of plant growth. Observe for the symptoms and signs on the infected plant parts. Count the number of leaves (leaf area diameter)/plant infected due to disease and incidence should be recorded.

**Stem, flower and fruit sampling:** Carefully examine the stems, flowers and fruits of plants for signs of fungal material diseases or lesions. The stems, flowers and fruits should be split or taken apart and examined for discoloration caused by fungi and bacteria. Count the number of plant, flower and fruit infected due to disease and incidence should be recorded.

**C. Surveillance through pheromone/attractant trap catches:**

Attractant traps for fruit fly with methyl eugenol/cue lure @ 1 trap per 5 tree have to be installed. Fix the traps to the supporting pole at mid canopy level. Change the lures at regular interval. During each week of surveillance, the number of number fruit flies/trap should be counted and recorded. The trapped fruit flies should be removed and destroyed after each recording.

**D. Yellow pan water/ sticky traps:**

Set up yellow pan water traps on the ground or yellow sticky traps at mid canopy level for monitoring leaf miner and white flies @ 1traps/per 5 trees. Locally available empty tins can be painted yellow coated with grease/Vaseline/castor oil on outer surface may also be used as yellow sticky trap.
III. ECOLOGICAL ENGINEERING FOR PEST MANAGEMENT

Ecological engineering for pest management has recently emerged as a paradigm for considering pest management approaches that rely on the use of cultural techniques to effect habitat manipulation and to enhance biological control. Ecological engineering for pest management is based on informed ecological knowledge rather than high technology approaches such as synthetic pesticides and genetically engineered crops (Gurr et al. 2004 a, b).

Ecological Engineering for Pest Management – Below Ground:

There is a growing realization that the soil borne, seed and seedling borne diseases can be managed with microbial interventions, besides choosing appropriate plant varieties. The following activities increase the beneficial microbial population and enhance soil fertility.

- Keep soils covered year-round with living vegetation and/or tree residue.
- Add organic matter in the form of farm yard manure (FYM), vermicompost, crop residue which enhance below ground biodiversity of beneficial microbes and insects.
- Application of balanced dose of nutrients using biofertilizers based on soil test report.
- Application of biofertilizers with special focus on mycorrhiza and plant growth promoting rhizobia (PGPR)
- Application of \textit{Trichoderma harzianum/viride} and \textit{Pseudomonas fluorescens} for treatment of seeds/ seedlings/planting materials in the nurseries and field (if commercial products are used, check for label claim. However, biopesticides produced by growers for own consumption in their fields, registration is not required).

Ecological Engineering for Pest Management – Above Ground:

Natural enemies play a very significant role in control of foliar insect pests. Natural enemy diversity contributes significantly to management of insect pests both below and above ground.

Natural enemies may require:

1. Food in the form of pollen and nectar.
2. Shelter, overwintering sites and moderate microclimate etc.
3. Alternate hosts when primary hosts are not present.

In order to attract natural enemies following activities should be practiced:

- Raise the flowering plants / compatible cash crops along the orchard border by arranging shorter plants towards main crop and taller plants towards the border to attract natural enemies as well as to avoid immigrating pest population
- Grow flowering plants on the internal bunds inside the orchard
- Not to uproot weed plants those are growing naturally such as \textit{Tridax procumbens}, \textit{Ageratum} sp, \textit{Alternanthera} sp etc. which act as nectar source for natural enemies
- Not to apply broad spectrum chemical pesticides, when the P:D ratio is favourable. The plant compensation ability should also be considered before applying chemical pesticides.
- Reduce tillage intensity so that hibernating natural enemies can be saved.
- Select and plant appropriate companion plants which could be trap crops and pest repellent crops. The trap crops and pest repellent crops will also recruit natural enemies as their flowers provide nectar and the plants provide suitable microclimate.

Due to enhancement of biodiversity by the flowering plants, parasitoids and predators (natural enemies) number also will increase due to availability of nectar, pollen and insects etc. The major predators are a wide variety of spiders, ladybird beetles, long horned grasshoppers, lacewing, earwigs, etc.
Plants Suitable for Ecological Engineering for Pest Management

Attractant Plants

Lablab bean  Cowpea  Carrot

Sunflower  Buckwheat  Alfalfa

Maize  Mustard  French bean

Marigold  Coriander  Chrysanthemum

The flowering plants suggested under Ecological Engineering for pest management strategy are known as attractant plants to the natural enemies of the selected pests. The information is based on published literature, however, the actual selection of flowering plants could be based on availability, agro-climatic conditions and soil types.
Biodiversity of natural enemies observed in Ecological Engineering field at NIPHM

Biodiversity of natural enemies: Parasitoids

Biodiversity of natural enemies: Predators

Biodiversity of natural enemies: Spiders
AESA based IPM – Sapota

IV. RESISTANT/TOLERANT VARIETIES

<table>

<td></td>
</tr>
<tr>
<td>• Timely planting should be done.</td>
<td></td>
</tr>
<tr>
<td>• Plant material for laying quality fruit orchard should be obtained from registered nursery.</td>
<td></td>
</tr>
<tr>
<td>• Avoid planting of saplings infested with scales, borers and diseases.</td>
<td></td>
</tr>
<tr>
<td>• Don’t grow the nursery at the same site every year.</td>
<td></td>
</tr>
<tr>
<td>• Use of disease-resistant rootstock and scion for managing the collar rot.</td>
<td></td>
</tr>
<tr>
<td>• For raising of nurseries, the soil selection be made which is free from pest infestation.</td>
<td></td>
</tr>
</tbody>
</table>
Delay planting until the soil is reasonably dry and plant before the buds begin to burst.
Growing of flowering plants especially marigold and maize on the peripheries will help in conservation of both predators and parasites. In rich soils, the fertilizer doses may be half or applied on the basis of leaf analysis report.
Make use of neem cakes while raising plant nurseries to ward off any soil pest.

* Apply *Trichoderma viride/harzianum* and *Pseudomonas fluorescens* for nursery treatment and soil application (if commercial products are used, check for label claim. However, biopesticides produced by farmers for own consumption in their fields, registration is not required).

### Vegetative stage (2nd to 4th years)

#### Common cultural practices:
- Collect and destroy diseased and insect infected plant parts.
- Provide irrigation at critical stages of the crop
- Avoid water stagnation.

#### Common mechanical practices:
- Collection and destruction of eggs and early stage larvae
- Handpick the older larvae during early stages
- The infested curd and seed capsules may be collected and destroyed
- Handpick the gregarious caterpillars and the pupae which are found on leaves and destroy them in kerosene mixed water.
- Use light trap @ 1/acre and operate between 6 pm and 10 pm
- Set up bonfire during evening hours at 7-8 pm

#### Common biological practices:
- Conserve natural enemies through ecological engineering
- Augmentative release of natural enemies.
- Enhance parasitic activity by avoiding chemical spray, when 1-2 larval parasitoids are observed.

#### Nutrients
- Apply fertilizers according to the age of plant as mentioned below;

<table>
<thead>
<tr>
<th>Age of the tree</th>
<th>Nitrogen (grams/tree)</th>
<th>Phosphorus</th>
<th>Potash</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-3 Years</td>
<td>50</td>
<td>25</td>
<td>75</td>
</tr>
<tr>
<td>4-6 Years</td>
<td>100</td>
<td>40</td>
<td>150</td>
</tr>
<tr>
<td>7-10 years</td>
<td>200</td>
<td>80</td>
<td>300</td>
</tr>
<tr>
<td>11 years and onward</td>
<td>400</td>
<td>160</td>
<td>450</td>
</tr>
</tbody>
</table>

#### Weeds
- Cultural control:
  - Use black polythene mulch for suppressing the weeds growth.
  - Remove the existing weeds around the pits by using hand tools as and when required.
  - Inter-cultivation by suitable plough or cultivator between the rows of sapota plants immediately after onset of the monsoon and may be repeated after suitable interval.

#### Bud worm/ bud borer
- Cultural control:
  - Plough around trees to expose and kill pupae
  - Collect and destroy damaged buds along with caterpillar
  - Soil raking etc.

VI. INSECTICIDE RESISTANCE AND ITS MANAGEMENT

**Insecticide resistance:** Resistance to insecticides may be defined as ‘a heritable change in the sensitivity of a pest population that is reflected in the repeated failure of a product to achieve the expected level of control when used according to the label recommendation for that pest species’ (IRAC). Cross-resistance occurs when resistance to one insecticide confers resistance to another insecticide, even where the insect has not been exposed to the latter product.

**Causes of resistance development:** The causes and rate at which insecticide resistance develops depend on several factors, including the initial frequency of resistance alleles present in the population, how rapidly the insects reproduce, the insects’ level of resistance, the migration and host range of the insects, the insecticide’s persistence and specificity, and the rate, timing and number of applications of insecticide made. For instance, insect pests that survive in large populations and breed quickly are at greater advantage of evolving insecticide, especially when insecticides are misused or over-used.

**General strategy for insecticide resistance management:** The best strategy to avoid insecticide resistance is prevention and including insecticide resistance management tactics as part of a larger integrated pest management (IPM) approach.

1) **Monitor pests:** Monitor insect population development in fields to determine if and when control measures are warranted. Monitor and consider natural enemies when making control decisions. After treatment, continue monitoring to assess pest populations and their control.

2) **Focus on AESA.** Insecticides should be used only as a last resort when all other non-chemical management options are exhausted and P: D ratio is above 2: 1. Apply biopesticides/chemical insecticides judiciously after observing unfavourable P: D ratio and when the pests are in most vulnerable life stage. Use application rates and intervals as per label claim.

3) **Ecological engineering for pest management:** Flowering plants that attract natural enemies as well as plants that repel pests can be grown as border/intercrop.

4) **Take an integrated approach to managing pests.** Use as many different control measures as possible viz., cultural, mechanical, physical, biological etc. Select insecticides with care and consider the impact on future pest populations and the environment. Avoid broad-spectrum insecticides when a narrow-spectrum or more specific insecticide will work. More preference should be given to green labeled insecticides.

5) **Mix and apply carefully.** While applying insecticides care should be taken for proper application of insecticides in terms of dose, volume, timing, coverage, application techniques as per label claim.

6) **Alternate different insecticide classes.** Avoid the repeated use of the same insecticide, insecticides in the same chemical class, or insecticides in different classes with same mode of action and rotate/alternate insecticide classes and modes of action.

7) **Preserve susceptible genes.** Preserve susceptible individuals within the target population by providing unsprayed areas within treated fields, adjacent “refuge” fields, or habitat attractions within a treated field that facilitate immigration. These susceptible individuals may outcompete and interbreed with resistant individuals, diluting the resistant genes and therefore the impact of resistance.
## VII. NUTRITIONAL DEFICIENCIES

<table>
<thead>
<tr>
<th>Nutrients</th>
<th>Appearance</th>
</tr>
</thead>
</table>
| **Nitrogen**: Stunted growth. The bark of the shoots turn reddish-brown in colour. On elongating shoots, the immature leaves become amber to bright red while the mature leaves remained small and yellow-green in colour. Early abscission of leaves, smaller and fewer fruits.  
Correction measure: Foliar sprays of urea @ 2% with 250 g N per tree from both sources increase the fruit weight and yield. | ![Nitrogen deficiency](image1.png) |
| **Phosphorus**: Pigmentation seen in older leaves; leaf size become small.  
Correction measure: Foliar spray of DAP 2% at fortnightly intervals. | ![Phosphorus deficiency](image2.png) |
| **Potassium**: Light brown specks scattered all over the leaves which appear later merged forming necrotic patches between the large veins. Browning on the under side of the leaves and chlorotic areas between veins due to K deficiency.  
Correction measure: Application of KCl on soil test basis. | ![Potassium deficiency](image3.png) |
| **Calcium**: Tip of the twig and flower bud is affected and growth retarded.  
Correction measure: Apply gypsum of lime based on soil test recommendation. | ![Calcium deficiency](image4.png) |
| **Magnesium**: Leaves become lighter green which gradually turn greenish yellow, remaining deeper green along the mid rib and larger veins. Leaves turn yellow with scattered brown lesion on the leaf blade. Interveinial chlorosis on older leaves followed by necrosis of distal leaf edge.  
Correction measure: Application of dolomite or spraying magnesium nitrate @ 1% can avoid the deficiency. | ![Magnesium deficiency](image5.png) |

13. Purple nutsedge: *Cyperus rotundus* L. (Cyperaceae)
14. Flat sedge: *Cyperus iria* L. (Cyperaceae)
IX. DESCRIPTION OF INSECT PESTS

1) Leaf webber:

<table>
<thead>
<tr>
<th>Biology:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Egg:</strong> Eggs are laid usually in small batches of 4 to 30 along the mid rib of the underside of leaf or tender branches. Freshly laid eggs were soft, pale yellow but semi-transparent. The fertile eggs turn pink within 24 hrs.</td>
</tr>
<tr>
<td><strong>Larva:</strong> Neonate larvae measure 1.35 mm in length. Initially they are pink and become yellow within 24 h and later turns into greenish in colour. Head is pale yellow. Dorsal side of body is pink in colour while ventral side is green. First and third pair of strips are pink in colour blended with black spots on each segment while second pair is purple.</td>
</tr>
<tr>
<td><strong>Pupa:</strong> Pupation takes place in plant debris or in soil.</td>
</tr>
<tr>
<td><strong>Adult:</strong> Adult is grayish in colour with compound black eyes with setaceous antennae. Fore wings are grayish with four black transverse wavy lines. Hind wings are membranous white. Both the wings are fringed at the outer margins. A brownish line is present near the outer margins of the wings.</td>
</tr>
</tbody>
</table>

**Damage symptoms:**
Caterpillar webs and feed on leaves by scrapping chlorophyll content. Caterpillar also bores into flower buds and tender fruits leading to withering and shedding.

*For management refer to page number 15*

2) Green scale:

<table>
<thead>
<tr>
<th>Biology:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Egg:</strong> Eggs are whitish green elongate-oval and are laid singly. Eggs hatch beneath the female where they are protected. Eggs hatch from a few minutes to several hours after being laid</td>
</tr>
<tr>
<td><strong>Nymphs (crawlers):</strong> Nymphs, or immature green scales are oval, flat and yellowish green in color, and have six short legs. There are three nymphal stages before becoming an adult, each stage being larger and more convex than the previous stage</td>
</tr>
<tr>
<td><strong>Adults:</strong> The adult female is shiny pale green with a conspicuous black, irregular U-shaped internal marking that is dorsally visible to the naked eye. Two sub-marginal black eye spots are also present and can be seen with a hand lens. The outline shape may be described as elongate-oval and moderately convex. Adult scales are 2.5-3.25 mm. Dead scales are light brown or buff color and the black internal marking is lost.</td>
</tr>
</tbody>
</table>

**Life cycle:**

**Nature and symptoms of damage:**
Scales damage plants by sucking out plant sap as a result leaves turn to yellow and wilt.

**Natural enemies of scale insects:**
- **Parasitoids:** Coccophagus cowperi
- **Predators:** Cryptolaemus montrouzieri

*For management refer to page number 15*
3) Mealybug:

**Biology:** Mealybugs are soft pinkish-white insects with a waxy appearance. Adult females are soft-bodied, wingless insects that grow between 1/20 and 1/5 inch long. Mealybugs lay large clusters of several hundred eggs on the surface of a leaf, which then hatch into yellow nymphs, which feed on plant sap.

**Life cycle:**

<table>
<thead>
<tr>

**Natural enemies of mealybug:**
- **Parasitoids:** Parasitic wasp
- **Predators:** Hover flies, ladybird beetle, *Cryptolaemus montrouzieri*

*For management refer to page number 15

4) Fruit fly:

**Biology**

**Egg:** The eggs of *Bactrocera* species are very similar measuring 0.8 mm long, 0.2 mm wide, with the micropyle protruding slightly at the anterior end. The chorion is reticulate (requires scanning electron microscope examination). White to yellow-white in colour.

**Larva:** The third-instar, which has a typical maggot appearance, is about 10 mm in length and creamy white. The only band of spinules encircling the body is found on the first segment. The external part of the anterior respiratory organs, the spiracles, located one on each side of the pointed or head end of the larva, has an exaggerated and deflexed lobe at each side and bears many small tubercles. The caudal segment is very smooth. The posterior spiracles are located in the dorsal third of the segment as viewed from the rear of the larva. The mature larva emerges from the fruit, drops to the ground, and forms a tan to dark brown puparium about 4.9 mm in length. The entire larval stage lasts for 11-15 days.

**Pupa:** When mature, larvae drop to the ground and pupate in the soil. The puparium is yellowish-brown and seed-like. Adults emerge in about 10 days.

**Adult:** Generally, the abdomen has two horizontal black stripes and a longitudinal median stripe extending from the base of the third segment to the apex of the abdomen. These markings may form a "T" shaped pattern, but the pattern varies considerably. Females begin to lay eggs about 8 days after emergence from the puparium. Under optimum conditions, a female can lay more than 3,000 eggs during her lifetime, but under field conditions approximately 1,200 to 1,500 eggs per female is considered to be the usual production. Ripe fruit are preferred for egg laying, but immature ones may be also attacked.

**Life cycle:**

**Symptoms of damage:**
- Maggot bore into semi-ripen fruits with decayed spots and dropping of fruits.
- Oozing of fluid
- Brownish rotten patches on fruits

**Natural enemies of fruit fly:**
- **Parasitoids:** *Fopius arisanus, Diachasmimorpha kraussi* etc.

*For management refer to page number 16
5) Bud borer:

**Biology:**

**Egg:** The eggs are smooth, oval and white in colour at the time of oviposition and turned to light brown before hatching. The length of eggs ranged from 0.37 to 0.49 mm with an average of 0.46 mm, while the breadth varied from 0.20 to 0.29 mm with an average of 0.25 mm. The incubation period varied from 4 to 6 days with an average of 4.64 days.

**Larva:** The larva is small, slender, pinkish brown with black head and passed through four instars on sapota buds. The newly hatched caterpillar was light yellow in colour, shiny with black head. It was tiny and delicate with slender body.

**Pupa:** This pre-pupal condition lasted for about one day during which the larva did not exhibit any movement unless it was disturbed. The prepupal period lasted for 1 to 2 days with an average of 1.52 days. The length of pre-pupa varied from 6.10 to 7.20 mm with an average of 6.62 mm, while breadth ranged from 1.61 to 2.10 with an average of 1.41 mm. A newly formed pupa was obtect type, brick-red in colour and changed into dark brown prior to the emergence as adult. The pupation took place either inside or out side of the flower buds.

**Adult:** Grey moth with black patch on wings. The adults development was completed and legs and the wings are clearly visible through the pupal skin under microscope.

**Damage symptoms:**

- The bud borer webs together flower buds and flowers and reported to cause huge damage ranged from 2-15%. The bud borer feeds by making holes into the petals and ovary resulting in significant crop loss. Larvae damages inflorescences of the trees.

*For management refer to page number 14

6) Seed Borer:

**Biology:**

**Egg:** A female moth lays eggs on medium sized immature fruits of sapota with the fecundity of 29 to 255 eggs/female.

**Larva:** The larvae are very minute, white in colour with pinkish tinge. The larvae feed only on endosperm of the seed and complete its larval period inside the seed. For pupation, the mature larva comes out by tunneling out the fruit which usually coincides with the fruit harvest.

**Damage symptoms:**

The seed borer is a monophagous pest attacking immature fruits of sapota. Neonate larva bores into the fruit and finally enters the seed. The larvae feed only on endosperm of the seed. Full grown larvae prepare a tunnel to come out for pupation. Due to the infestation of the pest, quality of the fruit deteriorates and hence the market price goes down.

*For management refer to page number 16.

7) Bud worm

**Biology:**

**Egg:** Female lays 50 -60 eggs in axils of the tender leaves, singly or in batches of 10-20, egg period is 3 days.

**Larva:** Larva is small, slender, pinkish brown in colour with black head and yellowish brown thoracic shield, larval period is 14-16 days.

**Pupa:** pupal period is 7-10 days.

**Adult:** Adult moth is grey coloured with black patches on wings. Life cycle completed in 24-29 days.

**Life cycle:**

**Damage symptoms:**

- Webbed flowers and buds
- Shedding of buds and flowers
- Bore holes and excreta seen on attacked flowers
- Floral buds and flowers webbed together by larvae and shed.

**Natural enemies of bud worm:**

**Parasitoid:** *Trichogramma* spp. etc.

**Predators:** Lacewings, robber fly, coccinellids, spiders, red ants, dragon fly, praying mantis, reduviid bugs etc

*For management refer to page number 14

8) Stem borer:

**Biology:**

**Egg:** Female lays ovoid, dirty white eggs under loose bark. Egg period is 4-6 days.

**Grub:** Full grown grub measures 7.5 cm and tunnels its way into the root region. Grub period is 6-7 months.

**Pupa:** Pupation occurs in a calcareous pupal chamber and pupal period is 60 days.

**Adult:** Adults lay eggs under loose bark in their early stages and into the wood in their late stages. Life cycle completed in one year.

**Life cycle:**

![Life cycle diagram of stem borer](image-url)

**Damage symptoms:**

- Symptoms of damage include presence of small holes at the collar region, gummosis, extrusion of frass through holes at the collar region, yellowing and shedding of leaves, drying up of twigs and gradual death of the tree.
- Presence of small holes at the collar region
- Gummosis
- Extrusion of frass through the bore holes at the collar region
- Yellowing and shedding of leaves
- Drying up of twigs and gradual death of the tree.
- Sometimes until the adults emerge, no damage symptoms are seen.

**Natural enemies of stem borer:**

**Predators:** *Chrysoperla zastrowi sillemi*, coccinellids, King crow, common mynah, wasp, dragonfly, spider, robber fly, reduviid bug, praying mantis, fire ants, big eyed bugs (*Geocoris* sp), pentatomid bug (*Eocanthecona fucellata*), earwigs, ground beetles, rove beetles etc.

*For management refer to page number 15.*

9) Hairy caterpillar:

**Biology:**

**Egg:** Egg period is 5-7 days.

**Larva:** Caterpillar is dirty brown in colour with whitish hairs arising in tufts on small warts. Hairs are poisonous and irritating. Head capsule and thoracic legs are coral red in colour. Larval period is 20-25 days.

**Pupa:** Larva pupates in soil in an earthen cocoon. Pupal period is 8-10 days.

**Adult:** It is a large moth with light yellowish brown wings, having faint lines. Female moth lays eggs in clusters on tender parts.

**Life cycle:**

![Life cycle diagram of hairy caterpillar](image-url)

**Damage symptoms:**

- Caterpillars gather in a cluster on the stem of the plants during hot hours of day
- They are active at night, defoliate the tree quickly and collect on the trunk
- The larva feeds on leaves causing defoliation

**Natural enemies of hairy caterpillar:**

**Predators:** Predatory ant, lacewings, ladybird beetles, King crow, common mynah, wasp, dragonfly, spider, robber fly, reduviid bug, praying mantis, fire ants, big eyed bugs (*Geocoris* sp), pentatomid bug (*Eocanthecona fucellata*), earwigs, ground beetles, rove beetles etc.

*For management refer to page number 15.*
10) Leaf miner:

**Biology:**

**Egg:** Eggs are very tiny. They are laid inside the leaf tissue, just below the leaf surface. In some instances eggs are laid below the epidermis of fruits/pods. Eggs hatch in about 3 days.

**Larva:** They are small yellow maggots. They are found feeding inside the leaf tissue, leaving long, slender, winding, white tunnels (mines) through the leaf. They pass through 3 larval stages. After 5 to 7 days the maggots leave the mines and pupate either on the leaf surface or - more commonly - in the soil. In some cases, maggots pupate within the mines.

**Pupa:** Pupae are very small, oval, slightly flattened ventrally with variable color varying from pale yellow-orange to golden-brown. They have a pair of cone-like appendages at the posterior end of the body. Adults emerge 4 to 5 days after pupation. In some cases, maggots pupate within the mines.

**Adult:** Adults are small, about 2 mm long. They are greyish to black with yellow markings. Female flies are slightly larger than males. The life cycle varies with host and temperature. The average life cycle is approximately 21 days in warm conditions, but can be as short as 15 days.

**Life cycle:**

- **Egg:**
- **Larva:**
- **Pupa:**
- **Adult:**

**Damage symptoms:**

- Drying and dropping of leaves

**Natural enemies of leaf miner:**

- **Parasitoids:** Gronotoma micromorpha, Diglyphus isaea, Halticoptera circulus, Opius phaseoli, Chrysocharis pentheus, Neochrysocharis formosa
- **Predators:** Lacewings, ladybird beetle, spiders, red ants etc.

*For management refer to page number 15

11) Spiraling whitefly:

**Biology:**

**Egg:** Female lays several (dozens) tiny, elliptical, smooth surfaced, yellow to tan eggs on lower surface of leaf along with numerous tiny waxy secretions making an irregular, waxy lines (spiraling pattern).

**Nymph:** Nymphs go through four instars (immature stages). The first three are referred to as larvae and continuously feed on plant sap. The first larval stage (“crawler”) is the only immature stage with functional legs (capable for active movement) and distinct antennae. All other immature stages are sedentary. Once the crawlers settle, they develop a characteristic row of mid-back waxy tufts on the anterior of their body which continue to grow as more material is secreted. During the third larval stage glass-like rods of wax appear along the sides of the body.

**Pupa:** The final and fourth immature stage is considered as pupa. This stage feeds during the earlier phases then stops feeding and undergoes internal tissue reorganization before moulting into an adult.

**Adult:** The adults are similar in appearance to many other species of whiteflies. They are white and quite small measuring 2-3 mm in length and coated with a fine dust-like waxy secretion. They somewhat resemble tiny moths, and both sexes are winged. The eyes of this whitefly are dark reddish-brown. Wings are transparent after emergence from the pupal casing, but develop a white powder covering after a few hours. The forewings each have two characteristic black spots. Females begin laying eggs within a day of emergence and continue to lay eggs throughout the lifetime. Unmated females produce only male progeny while mated females produce both sexes.
Life cycle:

1. Eggs
2. Nymph
3. Pupae
4. Adult

Damage symptoms:
- Chlorotic spots
- Yellowing
- Downward curling and drying of leaves
- Vector of leaf curl disease

Natural enemies of whitefly:
Parasitoids: Encarsia formosa, Eretmocerus spp., Chrysocharis pentheus etc.
Predators: Dicyphus hesperus, lacewing, ladybird beetle, big-eyed bugs (Geocoris sp) etc.

*For management refer to page number 15

12) Scale:

Biology:

Nymph: Female scales give birth to living young that emerge from under the edge of the scale covering. Each female gives birth to 200-400 nymphs. These tiny yellow crawlers wander in a random fashion until they find a suitable place to settle.

Adult: Immature male and female scales are indistinguishable until the first molt. At this time, the male scale covering begins to elongate, while the females remain circular. Males molt a total of four times. Following the final molt, adult male scales emerge from the scale covering as tiny, yellow winged insects. Female scales are very prolific and over a 6-week period can produce approximately 400 young. Crawlers move around for a short period in search of a suitable place to settle. It takes 25 days for males to mature and 31 days for females. Five to six generations in a year.

Life cycle:

1. Eggs
2. Nymphs
3. Adult

Damage symptoms:
- Nymph and female scales attack all above ground parts.
- Feeding site turns into a characteristic purplish red colour.
- Initially growth of plant is checked but as scale increases in number plant may die.
- Fruits will have distinct “measles” spots on the surface.

Natural enemies of scales:
Parasitoids: Encarsia sp., Aphytis sp., etc.,
Predator: Coccinellid (Pharoscymnus flexibilis) etc.

*For management refer to page number 15
Natural Enemies of Sapota Insect Pests

Parasitoids

1. *Coccophagus cowperi*
2. Parasitic wasp
3. *Fopius arisanus*
4. *Diachasmimorpha kraussii*

Predators

1. *Cryptolaemus montrouzieri*
2. Hover fly
3. Anthocorid bug
4. Ladybird beetle
5. Lacewing
6. Big-eyed bug (*Geocoris* sp)

X. DESCRIPTION OF DISEASES

1) Leaf spot:

**Disease symptoms:**
- Numerous, small, circular, pinkish to reddish brown, conspicuous spots with whitish center on mature leaves
- Spots coalesce and leaves drop prematurely.

**Survival and spread:**
- The pathogen is seed borne fungus and inoculum present in the seeds are source of primary infection. Fungus also survives on glumes, fruit and plant debris.

**Favourable conditions:**
- Rainy seasons favour the development of disease.
*For management refer to page number 15

2) Sooty mould:

**Disease symptoms:**
- It is a fungal disease developed on honeydew-like excretion secreted by aphids and scale insects.
- The fungus slowly covers the entire leaf area severely affecting the process of photosynthesis.
- This results in reduced translocation of food to the fruits, which leads to reduction in their size.

**Survival and spread:**
- The severity of infection depends on the honey dew secretions by the scale insects which provide the necessary medium for the fungal growth.
- Transmission occurs by air-borne ascospores.

**Favourable conditions:**
- High humidity and moist situation favours the development of disease.
*For management refer to page number 16

3) Fasiation:

**Disease symptoms:**
- Branches of affected trees become flat and twisted
- Leaves become thin, small and yellow
- Cluster of leaves and flowers on affected twigs
- Flowers remain infertile
- If fruits are set, they are undersized, hard and fail to ripen.

4) Postharvest diseases:

4.1) Soft rot:

**Disease symptoms:**
- The diseases appear as water-soaked spots covering the entire fruit within 3 to 4 days.
- Rotted fruits become soft and dark brown and later numerous acervuli are seen in rotted zones.
- The fungal colonies are yellowish white.
- Mycelium is branched & septate.
- Acervuli are black, globose to sub-globose
- Conidiophores are short and simple and conidia are fusiform, 4-septata.

**Survival and spread:**
- The pathogen is primarily a wound parasite and avoid injury to fruits.

**Favourable conditions:**
- Germination of spores is maximum at 30°C & do not germinate below 15°C or above 40°C with RH above 96%

*For management refer to page number 17.

### 4.2) Fruit rot:

**Disease symptoms:**
- Diseased fruits exhibited water-soaked lesions which become brown within 2 to 3 days. Subsequently the whole fruit is covered with tufts of mycelium

**Survival and spread:**
- Rain and the wind are conducive for spread.
- The pathogen produces a great number of sporangia and spores on the surface of diseased tissues principally when the temperature is near 25°C and this is an important sources of inoculum in the development of epidemics.
- Spores spread from the infected plant material or soil by rain splashes.

**Favourable conditions:**
- Cool, wet environmental conditions with high soil moisture favour disease development.
- High humidity, temperature from 28-32°C (25°C), poorly drained soils and injuries are favourable for initiation of disease.
- Close plantation.

*For management refer to page number 17.

### 5) Basal rot:

**Disease symptoms:**
- Shortly after infection, the internal tissue of the seed piece turns red and eventually black. The black coloration results from the production of fungal spores within the seed piece. Nodes act as partial barriers to the spread of rotting, but with susceptible varieties, entire seed pieces may become colonized by the fungus. The disease severely retards bud germination, shoot development and early shoot vigor. When severe, the disease may reduce germination over large areas.

**Survival, spread & favourable conditions:**
- The disease is essentially soilborne, being transmitted by the fungal spores present in the soil. The fungus is found mainly in the top 25 cm of the soil profile. Infection occurs through wind-blown or rain-splashed spores gaining entry through damaged tissue. Any factor that delays germination of the buds on the seed piece increases the likelihood of infection. Excessively deep planting, wet or dry soil conditions and low temperature are all conducive to the development of the disease.

### 6) Heart rot:

**Disease symptoms**
- The symptom starts at calyx disc of the fruit during rainy season. Affected area is covered with whitish cotton like growth which develops very fast as the fruit matures and pathogen is able to cover almost the entire surface within a period of 3-4 days during humid weather. Under high relative humidity, the fruits near the soil level covered with dense foliage are most severely affected. The fallen fruits are badly affected.
The skin of the fruit below the whitish cottony growth becomes a little soft, turns light brown to dark brown and emits a characteristic unpleasant smell. Ultimately such fruits drop off from the tree.

**Survival and spread:**
- Rain and the wind are conducive for spread.
- The pathogen produces a great number of sporangia and spores on the surface of diseased tissues principally when the temperature is near 25°C and this is an important source of inoculum in the development of epidemics.
- Spores spread from the infected plant material or soil by rain splashes.

**Favourable conditions:**
- Cool, wet environmental conditions with high soil moisture favour disease development.
- High humidity, temperature from 28-32°C (25°C), poorly drained soils and injuries are favourable for initiation of disease. Close plantation.

*For management refer to page number 16.

### 7) Anthracnose:

**Disease symptoms:**
- The disease causes serious losses to young shoots, flowers and fruits. It also affects fruits during storage.
- The disease produces leaf spot, blossom blight, withertip, twig blight and fruit rot symptoms.
- Tender shoots and foliage are easily affected which ultimately cause die back of young branches. Older twigs may also be infected through wounds which in severe cases may be fatal.
- Depending on the prevailing weather conditions blossom blight may vary in severity from slight to a heavy infection of the panicles. Black spots develop on panicles as well as on fruits. Severe infection destroys the entire inflorescence resulting in no setting of fruits.
- Young infected fruits develop black spots, shrivel and drop off.
- Fruits infected at mature stage carry the fungus into storage and cause considerable loss during storage, transit and marketing.

**Survival and spread:**
- Fungus survives in dead twig and other host for long time which is the source of primary infection.

**Favourable conditions:**
- High humidity, frequent rains and a temperature of 24-32°C favours the development of disease.

*For management refer to page number 16.

**Disease cycles:**

1. **Sooty mould:**
   - Primary spread occurs by airborne spore.
   - Secondary spread of disease occurs by infected plant parts.

2. **Leaf spot:**
   - The conidia of the fungus are carried by wind, rain water and old dried infected leaves and they help to spread the disease.
   - Secondary spread by conidia.
XI. SAFETY MEASURES

A. At the time of harvest:

**Harvest the fruit when:**

- The brown scaly external material from the fruit sheds off.
- Fruit becomes corky brown in color.
- Latex does not flow when the fruit is scratched with the finger nail.

**Precautions:**

- Harvest with the use of appropriate harvesting tools.
- Detached fruits must not be allowed to fall to the ground.

B. During post-harvest storage:

- Fruit must be carefully handled in order to prevent bruising and wounding.
- Harvested fruit must not be exposed to direct sunlight, but should be kept under shade.
- Harvested fruit must be collected in clean and dry plastic crates.
- Defective fruits, i.e., those that are diseased, mechanically damaged and not marketable must be separated out.
- Fruits must be cleaned by wiping or brushing. They must not be immersed in water as the corky fruit peel can retain moisture.
- Fruits must be transported during the cooler part of the day, in well ventilated plastic crates under clean and dry conditions.
- Wetting of fruit during transportation must be avoided.
- Fruit must be transported as quickly as possible to the final destination, to prevent spoilage.
- Fruit destined for export must be packed in cardboard cartons lined with shredded paper to protect against injury.

**Storage**

- **Ambient conditions:** For temporary storage under ambient conditions, fruit must be stored in a cool, dry place with adequate ventilation.
- **Cold storage:** The fruits can be transported and stored at 13–15° C and a relative humidity 85–90%

</tbody>
</table>
XIII. BASIC PRECAUTIONS IN PESTICIDE USAGE

A. Purchase
1. Purchase only just required quantity e.g. 100, 250, 500, 1000 g/ml for single application in specified area.
2. Do not purchase leaking containers, loose, unsealed or torn bags; Do not purchase pesticides without proper/approved labels.
3. While purchasing insist for invoice/bill/cash memo

B. Storage
1. Avoid storage of pesticides in house premises.
2. Keep only in original container with intact seal.
3. Do not transfer pesticides to other containers; Do not expose to sunlight or rain water; Do not store weedicides along with other pesticides.
4. Never keep them together with food or feed/fodder.
5. Keep away from reach of children and livestock.

C. Handling
1. Never carry/transport pesticides along with food materials.
2. Avoid carrying bulk pesticides (dust/granules) on head shoulders or on the back.

D. Precautions for preparing spray solution
1. Use clean water.
2. Always protect your nose, eyes, mouth, ears and hands.
3. Use hand gloves, face mask and cover your head with cap.
4. Use polythene bags as hand gloves, handkerchiefs or piece of clean cloth as mask and a cap or towel to cover the head (Do not use polythene bag contaminated with pesticides).
5. Read the label on the container before preparing spray solution.
6. Prepare the spray solution as per requirement
7. Do not mix granules with water; Do not eat, drink, smoke or chew while preparing solution.
8. Concentrated pesticides must not fall on hands etc while opening sealed container. Do not smell pesticides.
9. Avoid spilling of pesticides while filling the sprayer tank.
10. The operator should protect his bare feet and hands with polythene bags.

E. Equipments
1. Select right kind of equipment.
2. Do not use leaky and defective equipments.
3. Select right kind of nozzles.
4. Don’t blow/clean clogged nozzle with mouth. Use old tooth brush tied with the sprayer and clean with water.
5. Do not use same sprayer for weedicide and insecticide.

F. Precautions for applying pesticides
1. Apply only at recommended dose and dilution.
2. Do not apply on hot sunny day or strong windy condition; Do not apply just before the rains and after the rains; Do not apply against the windy direction.
3. Emulsifiable concentrate formulations should not be used for spraying with battery operated ULV sprayer.
4. Wash the sprayer and buckets etc with soap water after spraying.
5. Containers buckets etc used for mixing pesticides should not be used for domestic purpose.
6. Avoid entry of animals and workers in the field immediately after spraying.
7. Avoid tank mixing of different pesticides.

G. Disposal
1. Left over spray solution should not be drained in ponds or water lines etc. throw it in barren isolated area if possible.
2. The used/empty containers should be crushed with a stone/stick and buried deep into soil away from water source.
3. Never reuse empty pesticides container for any other purpose.

<tr>
<td>2.</td>
<td>It is advisable to check the output of the sprayer (calibration) before commencement of spraying under guidance of trained person.</td>
</tr>
<tr>
<td>3.</td>
<td>Clean and wash the machines and nozzles and store in dry place after use.</td>
</tr>
<tr>
<td>4.</td>
<td>It is advisable to use protective clothing, face mask and gloves while preparing and applying pesticides. Do not apply pesticides without protective clothing and wash clothes immediately after spray application.</td>
</tr>
<tr>
<td>5.</td>
<td>Do not apply in hot or windy conditions.</td>
</tr>
<tr>
<td>6.</td>
<td>Operator should maintain normal walking speed while undertaking application.</td>
</tr>
<tr>
<td>7.</td>
<td>Do not smoke, chew or eat while undertaking the spraying operation</td>
</tr>
<tr>
<td>8.</td>
<td>Operator should take proper bath with soap after completing spraying</td>
</tr>
<tr>
<td>9.</td>
<td>Do not blow the nozzle with mouth for any blockages. Clean with water and a soft brush.</td>
</tr>

Important Natural Enemies of Sapota Insect Pests

Parasitoids

- Coccophagus cowperi
- Parasitic wasp
- Fopios arisanus
- Diachasmimorpha kraussi

Predators

- Cryptolaemus montrouzieri
- Hover fly
- Ladybird beetle
- Geocoris spp.
- Lacewing
- Big-eyed bug

Plants Suitable for Ecological Engineering in Sapota Orchard

- Lablab bean
- Cowpea
- Carrot
- Sunflower
- Buckwheat
- Alfalfa
- Maize
- Mustard
- French bean
- Marigold
- Coriander
- Chrysanthemum
