Balaji Scan Pvt. Ltd., Tel: 040-2330 3424
Important Natural Enemies of Papaya Insect Pests

Parasitoids

- Aphidius spp.
- Aphelinus spp.
- Encarsia formosa
- Eretmocerus spp.
- Anagrus flaveolus
- Stethynium triclavatum

Predators

- Robber fly
- Red ant
- Ladybird beetle
- Spider
- Praying mantis
- Black drongo

Plants Suitable for Ecological Engineering in Papaya Plantation

- Alfalfa
- Sunflower
- Ocimum spp.
- Chrysanthemum spp.
- Spearmint
- Mustard
- Marigold
- Carrot
- French bean
- Cowpea
- Buckwheat
- Maize
The AESA based IPM – Papaya, was compiled by the NIPHM working group under the Chairmanship of Dr. Satyagopal Korlapati, IAS, DG, NIPHM, and guidance of Shri. Utpal Kumar Singh JS (PP). The package was developed taking into account the advice of experts listed below on various occasions before finalization.

**NIPHM Working Group:**

**Chairman:** Dr. Satyagopal Korlapati, IAS, Director General  
**Vice-Chairmen:** Dr. S. N. Sushil, Plant Protection Advisor  
Dr. P. Jeyakumar, Director (PHM)

**Core Members:**
1. Er. G. Shankar, Joint Director (PHE), Pesticide Application Techniques Expertise.  
2. Dr. O. P. Sharma, Joint Director (A & AM), Agronomy Expertise.  
3. Dr. Satish Kumar Sain, Assistant Director (PHM), Pathology Expertise.  
4. Dr. Dhana Raj Boina, Assistant Director (PHM), Entomology Expertise.  
5. Dr. M. N. Reddy, Assistant Scientific Officer (PHM), Entomology Expertise.

**Other Member:**
1. Dr. B. S. Sunanda, Assistant Scientific Officer (PHM), Nematology Expertise.

**Contributions by DPPQ&S Experts:**
1. Shri. Ram Asre, Additional Plant Protection Advisor (IPM)  
2. Shri. R. Murali, Deputy Director (Entomology)  
3. Dr. Sanjay Arya, Deputy Director (Plant Pathology)  
4. Dr. Subhash Kumar, Deputy Director (Weed Science)

**Contributions by External Experts:**
1. Dr. A.K. Saxena, Principal Scientist, IIHR, Bangalore  
2. Dr. A.K. Mishra, Principal Scientist and Head, Division of Crop Protection, Central Institute for Subtropical Horticulture, Lucknow, U.P.  
3. Dr. H.P. Patnik, Prof & Head (Entomology), College of Agriculture, Odisha Univ. of Agriculture and Technology, Bhubaneswar-751003, Orissa.  
4. Dr. K.C. Sahu, Prof & Head (Pathology), College of Agriculture, Odisha Univ. of Agriculture and Technology, Bhubaneswar-751003, Orissa.  
5. Dr. S. N. Mohapatra, Prof & Head (Nematology), College of Agriculture, Odisha Univ. of Agriculture and Technology, Bhubaneswar-751003, Orissa.  
6. Dr. B.R. Patel, Prof & Head (Entomology), C.P. College of Agriculture, S.D. Agriculture University, Sardarkrushinagar-385506  
7. Dr. Surajit Khalko, Assistant Prof (Pathology), Uttar Banga Krishi Vishwavidyalaya, Cooch Behar, West Bengal  
8. Dr. Nripendra Laskar, Assistant Prof (Entomology), Uttar Banga Krishi Vishwavidyalaya, Cooch Behar, West Bengal  
9. Dr. Ayon Roy, Associate Prof (Pathology), Uttar Banga Krishi Vishwavidyalaya, Cooch Behar, West Bengal  
10. Dr. Tapan Kumar Hath, Prof (Entomology), Uttar Banga Krishi Vishwavidyalaya, Cooch Behar, West Bengal  
11. Dr. M. L. Kewat, Prof (Agronomy), Jawarlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (M.P)  
12. Dr. Nayak, Prof (Agronomy), Jawarlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (M.P)  
13. Dr. R. Pachori, Prof (Entomology), Jawarlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (M.P)  
14. Dr. S.B. Das, Prof (Entomology), Jawarlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (M.P)  
15. Dr. Om Gupta, Prof (Pathology), Jawarlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (M.P)  
16. Dr. Jayant Bhatt, Prof (Pathology), Jawarlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (M.P)  
17. Dr. A.K. Rawat, Prof (Soil Science), Jawarlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (M.P)  
18. Dr. H.K. Rai, Prof (Soil Science), Jawarlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (M.P)  
19. Dr. H.S. Yadava, Director of Research Services, Rajmata Vijayaraje Scindia Krishi Vishwa Vidyalaya, Gwalior – 474002, M.P.

**Information on Region-wise Distribution of Pests Provided by:**
1. Dr. N. Sathyanarayana, Director, Plant Biosecurity Division, NIPHM  
2. Mrs. S. Latha, Scientific Officer, Plant Biosecurity Division, NIPHM
FOREWORD

Intensive agricultural practices relying heavily on chemical pesticides are a major cause of widespread ecological imbalances resulting in serious problems of insecticide resistance, pest resurgence and pesticide residues. There is a growing awareness world over on the need for promoting environmentally sustainable agriculture practices.

Integrated Pest Management (IPM) is a globally accepted strategy for promoting sustainable agriculture. During last century, IPM relied substantially on economic threshold level and chemical pesticides driven approaches. However, since the late 1990s there is conscious shift to more ecologically sustainable Agro-Eco System Analysis (AESA) based IPM strategies. The AESA based IPM focuses on the relationship among various components of an agro-ecosystem with special focus on pest-defender dynamics, innate abilities of plant to compensate for the damages caused by the pests and the influence of abiotic factors on pest buildup. In addition, Ecological Engineering for pest management - a new paradigm to enhance the natural enemies of pests in an agro-ecosystem is being considered as an important strategy. The ecological approach stresses the need for relying on bio intensive strategies prior to use of chemical pesticides.

Sincere efforts have been made by resource personnel to incorporate ecologically based principles and field proven technologies for guidance of the extension officers to educate, motivate and guide the farmers to adopt AESA based IPM strategies, which are environmentally sustainable. I hope that the AESA based IPM packages will be relied upon by various stakeholders relating to Central and State government functionaries involved in extension and Scientists of SAUs and ICAR institutions in their endeavour to promote environmentally sustainable agriculture practices.

Date: 6.3.2014

(Avinash K. Srivastava)
FOREWORD

IPM as a holistic approach of crop protection based on the integration of multiple strategies viz., cultural, physical, mechanical, biological, botanical and chemical. Over the years IPM underwent several changes, shifting its focus from damage boundary, economic injury to economic threshold. Currently most stakeholders rely upon economic threshold levels (ETL) and tend to apply chemical pesticides at the first instance in the event of a pest attack, through Government of India has advocated need based and judicious application of chemicals. This approach is likely to cause adverse effects on agro-ecosystems and increase the cost of agricultural production due to problems of pest resurgence, insecticide resistance and sustainability.

During the late 90s FAO started advocating Agro-Ecosystem Analysis (AESA) based IPM. Experience in different countries have shown that AESA, which takes into account ecological principles and relies on the balance that is maintained by biotic factors in an ecosystem has also resulted in reduction in cost of production and increase in yields. AESA based IPM also takes into account the need for active participation of farmers and promotes experiential learning and discovery based decision making by farmers. AESA based IPM in conjunction with ecological engineering for pest management promotes bio-intensive strategies as against current chemical intensive approaches, while retaining the option to apply chemical pesticides judiciously as a measure of last resort.

The resource persons of NIPHM and DPPQ&S have made sincere efforts in revising IPM packages for different crops by incorporating agro-ecosystem analysis, ecological engineering, pesticide application techniques and other IPM options with the active cooperation of crop based plant protection scientists working in state Agricultural Universities and ICAR institutions. I hope this IPM package will serve as a ready reference for extension functionaries of Central / State Governments, NGOs and progressive farmers in adopting sustainable plant protection strategies by minimizing the dependence on chemical pesticides.

(Utpal Kumar Singh)
PREFACE

Need for environmentally sustainable agricultural practices is recognised worldwide in view of the wide spread ecological imbalances caused by highly intensive agricultural systems. In order to address the adverse impacts of chemical pesticides on agro-ecosystems, Integrated Pest Management has evolved further from ETL based approach to Agro-ecosystem Analysis based Integrated Pest Management (IPM).

In AESA based IPM the whole agro-ecosystem, plant health at different stages, built-in-compensation abilities of the plant, pest and defender population dynamics, soil conditions, climatic factors and farmers’ past experience are considered. In AESA, informed decisions are taken by farmers after field observation, AESA chart preparation followed by group discussion and decision making. Insect zoo is created to enable the farmer understand predation of pests by Natural Enemies. AESA based PHM also results in reduction of chemical pesticide usage and conserves the agro-ecosystems.

Ecological Engineering for Pest Management, a new paradigm, is gaining acceptance as a strategy for promoting Biointensive Integrated Pest Management. Ecological Engineering for Pest Management relies on cultural practices to effect habitat manipulation and enhance biological control. The strategies focus on pest management both below ground and above ground. There is growing need to integrate AESA based IPM and principles of ecological engineering for pest management.

There is a rising public concern about the potential adverse effects of chemical pesticides on the human health, environment and biodiversity. The intensity of these negative externalities, through cannot be eliminated altogether, can be minimized through development, dissemination and promotion of sustainable biointensive approaches.

Directorate of Plant Protection Quarantine and Storage (DPPQS), has developed IPM package of practices during 2001 and 2002. These packages are currently providing guidance to the Extension Officers in transferring IPM strategies to farmers. These IPM package of practices, have been revised incorporating the principles of AESA based IPM in detail and also the concept of Ecological Engineering for Pest Management. It is hoped that the suggested practices, which aim at enhancing biodiversity, biointensive strategies for pest management and promotion of plant health, will enable the farmers to take informed decisions based on experiential learning and it will also result in use of chemical pesticides only as a last resort & in a safe and judicious manner.

**AESA BASED IPM PACKAGE FOR PAPAYA**

Papaya-Plant description:

The papaya (Carica papaya L.; Family: Caricaceae), papaw, or pawpaw is native to the tropics of the Americas, perhaps from southern Mexico and neighboring Central America. The papaya is a large, tree-like plant, with a single stem growing from 5 to 10 m tall, with spirally arranged leaves confined to the top of the trunk. The lower trunk is conspicuously scarred where leaves and fruit were borne. The leaves are large, 50–70 cm in diameter, deeply palmately lobed, with seven lobes. Unusually for such large plants, the trees are dioecious. The tree is usually un-branched, unless lopped. They appear on the axils of the leaves, maturing into large fruit - 15–45 cm long and 10–30 cm in diameter. The fruit is ripe when it feels soft and its skin attains an-amber to orange hue.

India is the leading papaya producer, with a 38.61 percent share of the world production during 2008–2010, followed by Brazil (17.5%) and Indonesia (6.89%). Papaya fruit is a source of nutrients such as provitamin A carotenoids, vitamin C, folate and dietary fiber. Papaya skin, pulp and seeds also contain a variety of phytochemicals, including lycopene and polyphenols. The ripe fruit of the papaya is usually eaten raw, without skin or seeds.

**I. PESTS**

A. **Pests of National Significance**

1. **Insect pests**
   1.1 Mealybug: Paracoccus marginatus Williams & Granara de Willink (Hemiptera: Pseudococcidae)
   1.2 Grasshopper: Poecilocerus pictus Fab (Orthoptera: Pyrgomorphidae)

2. **Diseases**
   2.1 Stem or foot or collar rot: Pythium spp., Phytophthora spp., Rhizoctonia spp.
   2.2 Papaya ring spot disease: Papaya ring spot virus
   2.3 Papaya mosaic disease: Papaya mosaic virus (Potex virus)
   2.4 Anthracnose: Gloeosporium papayae P. Henn, Colletotrichum gloeosporioides (Penz.) Penz. & Sacc

Postharvest diseases

2.5 Anthracnose: Gloeosporium papayae P Henn
2.6 Rhizopus rot: Rhizopus stolonifer (Ehrenb.: Fr.) Vuill.
2.7 Fruit rot: Alternaria alternata (Fr.) Keissl.
2.8 Phomopsis rot: Phomopsis caricae-papayae Petr. & Cif.
2.9 Stem end rot: Botryodiplodia theobromae Leavitt and Munnecke (Lasiodiplodia theobromae)
3. **Nematode**
   3.1 Reniform nematode: *Rotylenchulus reniformis* Linford and Oliveira (Tylenchida: Hoplolaimidae)

4. **Weeds**
   **Broadleaf**
   4.1 Carrot grass: *Parthenium hysterophorus* L. (Asteraceae)
   4.2 Coat buttons: *Tridax procumbens* L. (Asteraceae)
   4.3 Yellow spider flower: *Cleome viscosa* L. (Capparidaceae)
   4.4 Asthma herb/Spurge: *Euphorbia hirta* L. (Euphorbiaceae)
   4.5 Cock’s comb: *Celosia argentea* L. (Amaranthaceae)
   4.6 Pigweed: *Amaranthus viridis* Hook. F. (Amaranthaceae)
   4.7 Goat weed: *Ageratum conyzoides* L. (Asteraceae)

**Grasses**
4.8 Large crabgrass: *Digitaria sanguinalis* (L.) (Poaceae)
4.9 Yellow foxtail: *Setaria glauca* (L.) P. Beauv. (Poaceae)
4.10 Goose grass: *Eleusine indica* (L.) Gaertner. (Poaceae)
4.11 Bermuda grass: *Cynodon dactylon* (L.) Pers. (Poaceae)

**Sedge**
4.12 Purple nutsedge: *Cyperus rotundus* L. (Cyperaceae)
4.13 Flat sedge: *Cyperus iria* L. (Cyperaceae)
4.14 Umbrella sedge: *Cyperus difformis* L. (Cyperaceae)

5. **Birds**
   5.1 Jungle crow: *Corrus macrocercus culminates* wagker (Passeriformes: Dicruridae)
   5.2 Myna: *Acridotheres tristis* L. (Passeriformes: Sturnidae)
   5.3 Roseinged parakeet: *Psittacula krameri* (Psittaciformes: Psittacidae)

**B. Pests of Regional Significance**

1. **Insect pests**
   1.1 Whitefly: *Bemisia tabaci* Gennadius (Hemiptera: Aleyrodidae) (Bihar, West Bengal, Gujrat, Karnataka)
   1.2 Scale insect: *Aspidiotus destructor* (Signoret) (Hemiptera: Diaspididae) (Andhra Pradesh)
   1.3 Aphids: *Aphis gossypii* Glover, *Myzus persicae* Sulzer (Hemiptera: Aphididae)
   1.4 Fruit flies: *Bactrocera diversus* (Coquillett), *B. cucurbitae* (Coquillett) (Diptera: Tephritidae)
   1.5 Grey weevil: *Mylocerus viridans* (Coleoptera: Curculionidae)
   1.6 Stem borer: *Dasyses rugosellus*

2. **Diseases**
   2.2 Powdery mildew: *Oidium caricae* F. Noack (New Delhi, Uttar Pradesh, Karnataka)
   2.3 Papaya leaf curl disease: *Papaya leaf curl virus* (Uttar Pradesh, Hisar, Maharashtra)

3. **Nematode**
   3.1 Root-knot nematode: *Meloidogyne incognita* (Uttar Pradesh, Madhya Pradesh, Karnataka)
II. AGRO-ECOSYSTEM ANALYSIS (AESA) BASED INTEGRATED PEST MANAGEMENT (IPM)

A. AESA:
The IPM has been evolving over the decades to address the deleterious impacts of synthetic chemical pesticides on environment ultimately affecting the interests of the farmers. The economic threshold level (ETL) was the basis for several decades but in modern IPM (FAO 2002) emphasis is given to AESA where farmers take decisions based on larger range of plantations observations. The health of a plant is determined by its environment which includes physical factors (i.e. soil, rain, sunshine hours, wind etc.) and biological factors (i.e. pests, diseases and weeds). All these factors can play a role in the balance which exists between herbivore insects and their natural enemies. Understanding the intricate interactions in an ecosystem can play a critical role in pest management.

Decision making in pest management requires a thorough analysis of the agro-ecosystem. Farmer has to learn how to observe the crop, how to analyze the field situation of the plantation and how to make proper decisions for their crop management. This process is called the AESA. Participants of AESA will have to make a drawing on a large piece of paper (60 x 80 cm), to include all their observations. The advantage of using a drawing is that it requires the participants/farmers to observe closely and intensively. It is a focal point for the analysis and for the discussions that follow, and the drawing can be kept as a record.

AESA is an approach, which can be gainfully employed by extension functionaries and farmers to analyze the field situations of the plantations with regards to pests, defenders, soil conditions, plant health and the influence of climatic factors and their relationship for growing a healthy crop. The basic components of AESA are:
- Plant health at different stages
- Built-in compensation abilities of plants
- Pest and defender population dynamics
- Soil conditions
- Climatic factors
- Farmers past experience

Principles of AESA based IPM:
Grow a healthy crop:
- Select a variety resistant/tolerant to major pests
- Select healthy seeds/seedlings/planting material
- Treat the seeds/seedlings/planting material with recommended pesticides especially biopesticides
- Follow proper spacing
- Soil health improvement (mulching and green manuring whenever applicable)
- Nutrient management especially organic manures and biofertilizers based on the soil test results. If the dose of nitrogenous fertilizers is too high the crop becomes too succulent and therefore susceptible to insects and diseases. If the dose is too low, the crop growth is retarded. So, the farmers should apply balanced dose of nitrogen for best results. The phosphatic fertilizers should not be applied each and every season as the residual phosphate of the previous season will be available for current season also.
- Proper irrigation
- Crop rotation
Observe the plantations regularly (climatic factors, soil and biotic factors):
Farmers should:
- Monitor the field situations of the plantations at least once a week (soil, water, plants, pests, natural enemies, weather factors etc.)
- Make decisions based on the field situations of the plantations and Pest: Defender ratio (P: D ratio)
- Take direct action when needed (e.g. collect egg masses, remove infested plants etc.)

Plant compensation ability:
Compensation is defined as the replacement of plant biomass lost to herbivores and has been associated with increased photosynthetic rates and mobilization of stored resources from source organs to sinks (e.g., from roots and remaining leaves to new leaves) during active vegetative growth period. Plant tolerance to herbivory can arise from the interaction of a variety of plant traits and external environmental factors. The ability of the plant to compensate for the reduced acquisition of resources by the production of new organs or by remobilization of reserves may also mitigate biotic stress effects.

Understand and conserve defenders:
- Know defenders/natural enemies to understand their role through regular observations of the agro-ecosystem.
- Avoid the use of chemical pesticides especially with broad-spectrum activity.

Model Agro-Ecosystem Analysis Chart

Soil conditions
Weather conditions
Diseases types and severity
Weeds types and intensity
Rodent damage (if any)
No. of insect pests
No. of natural enemies
P: D ratio

Decision taken based on the analysis of plantations situations
**Insect zoo:**
In plantations various types of insects are present. Some are beneficial and some may be harmful. Generally farmers are not aware about it. Predators (friends of the farmers) which feed on pests are not easy to observe in crop plantations. Insect zoo concept can be helpful to enhance farmers’ skill to identify beneficial and harmful insects. In this method, unfamiliar/unknown insects are collected in plastic containers with brush from the plantations and brought to a place for study. Each insect is placed inside a plastic bottle together with parts of the plant and some known insect pests. Insects in the bottle are observed for certain time and determined whether the test insect is a pest (feeds on plant) or a predator (feeds on other insects).

**Pest: Defender ratio (P: D ratio):**
Identifying the number of pests and beneficial insects helps the farmers to make appropriate pest management decisions. Sweep net, visual counts etc. can be adopted to arrive at the numbers of pests and defenders. The P: D ratio can vary depending on the feeding potential of natural enemy as well as the type of pest. The natural enemies of papaya insect pests can be divided into 3 categories 1. parasitoids; 2. predators; and 3. pathogens. The general rule to be adopted for management decisions relying on the P: D ratio is 2: 1. However, some of the parasitoids and predators will be able to control more than 2 pests. Wherever specific P: D ratios are not found, it is safer to adopt the 2: 1, as P: D ratio. Whenever the P: D ratio is found to be favourable, there is no need for adoption of other management strategies. In cases where the P: D ratio is found to be unfavourable, the farmers can be advised to resort to inundative release of parasitoids/predators depending upon the type of pest. In addition to inundative release of parasitoids and predators, the usage of microbial biopesticides and biochemical biopesticides such as insect growth regulators, botanicals etc. can be relied upon before resorting to synthetic chemical pesticides.

**Decision making:**
**Farmers become experts in crop management:**
Farmers have to make timely decisions about the management of their crops. AESA farmers have learned to make these decisions based on observations and analysis viz., abiotic and biotic factors of the crop ecosystem. The past experience of the farmers should also be considered for decision making. However, as plantations conditions continue to change and new technologies become available, farmers need to continue improving their skills and knowledge.

- Farmers are capable of improving farming practices by experimentation
- Farmers can share their knowledge with other farmers

**AESA methodology:**
- Go to the plantations in groups (about 5 farmers per group). Walk across the plantations and choose 20 plants/ acre randomly. Observe keenly each of these plants and record your observations:
  - Plant: Observe the plant height, number of leaves, crop stage, deficiency symptoms etc.
  - Insect pests: Observe and count insect pests at different places on the plant.
  - Defenders (natural enemies): Observe and count parasitoids and predators.
  - Diseases: Observe leaves and stems and identify any visible disease symptoms and severity.
  - Weeds: Observe weeds in the plantations and their intensity.
  - Water: Observe the moisture level of the plantations.
  - Weather: Observe the weather conditions.
- While walking in the plantations, manually collect insects in plastic bags. Use a sweep net to collect additional insects. Collect plant parts with disease symptoms.
- Find a shady place to sit as a group in a small circle for drawing and discussion.
- If needed, kill the insects with some chloroform (if available) on a piece of cotton.
- Each group will first identify the pests, defenders and diseases collected.
- Each group will then analyze the field situations of the plantations in detail and present their observations and analysis in a drawing (the AESA drawing).
- Each drawing will show a plant representing the field situations of the plantations. The weather conditions, water level, disease symptoms, etc. will be shown in the drawing. Pest insects will be drawn on one side. Defenders (beneficial insects) will be drawn on another side. Write the number next to each insect.
Indicate the plant part where the pests and defenders were found. Try to show the interaction between pests and defenders.

- Each group will discuss the situation and make a crop management recommendation.
- The small groups then join each other and a member of each group will now present their analysis in front of all participants.
- The facilitator will facilitate the discussion by asking guiding questions and makes sure that all participants (also shy or illiterate persons) are actively involved in this process.
- Formulate a common conclusion. The whole group should support the decision on what plantations management is required in the AESA plot.
- Make sure that the required activities (based on the decision) will be carried out.
- Keep the drawing for comparison purpose in the following weeks.

Data recording:
Farmers should record data in a notebook and drawing on a chart:

- Keep records of what has happened help us making an analysis and draw conclusions

Data to be recorded:

- Plant growth (weekly): Height of the plant, number of branches
- Crop situation (e.g. for AESA): Plant health; pests, diseases, weeds; natural enemies; soil condition; irrigation; weather conditions
- Input costs: Seeds; fertilizer; pesticides; labour
- Harvest: Yield (Kg/acre); price of produce (Rs./Kg)

Some questions that can be used during the discussion:

- Summarize the present situation of the plantations.
- What crop management aspect is most important at this moment?
- Is there a big change in crop situation compared to last visit? What kind of change?
- Is there any serious pest or disease outbreak?
- What is the situation of the beneficial insects?
- Is there a balance in the plantations between pests and defenders?
- Were you able to identify all pests and diseases?
- Do you think the crop is healthy?
- What management practices are needed at this moment?
- When will it be done? Who will do it? Make sure that responsibilities for all activities are being discussed.
- Are you expecting any problems to emerge during the coming week such as congenial weather conditions for pest buildup?
- What are the problems? How can we avoid it? How can we be prepared?
- Summarize the actions to be taken.

Advantages of AESA over ETL:
One of the problems of the ETL is that it is based on parameters that are changing all the time, and that are often not known. The damage or losses caused by a certain density of insects cannot be predicted at all. In ETL the due recognition of the role of natural enemies in decreasing pest population is ignored. Farmers cannot base their decisions on just a simple count of pests. They will have to consider many other aspects of the crop (crop ecology, growth stage, natural enemies, weather condition, etc.) and their own economic and social situation before they can make the right crop management decisions. In ETL based IPM, natural enemies, plant compensation ability and abiotic factors are not considered. In AESA based IPM emphasis is given to natural enemies, plant compensation ability, abiotic factors and P: D ratio.

AESA and farmer field school (FFS):
AESA is a season-long training activity that takes place in the farmer plantations. It is season-long so that it covers all the different developmental stages of the crop and their related management practices. The process is always learner-centered,
participatory and relying on an experiential learning approach and therefore it has become an integral part of FFS.

Farmer can learn from AESA:
- Identification of pests and their nature of damage
- Identification of natural enemies
- Management of pests
- Water and nutrient management
- Influence of weather factors on pest buildup
- Role of natural enemies in pest management

FFS to teach AESA based IPM skills:

B. Field scouting:

AESA requires skill. So only the trained farmers can undertake their exercise. However, other farmers also can do field scouting in their own plantationss at regular intervals to monitor the major pest situation.

Surveillance on pest occurrence at the main plantations should commence soon after crop establishment after transplanting and at weekly intervals thereafter. In each of the plantationss, select five spots randomly. Select five random plants at each spot for recording counts of insects as per procedure finalized for individual insects.

For insect pests:
- Aphid, whitefly, mealybug: Count and record the number of both nymphs and adults on five randomly selected leaves per plant.
- Scale insects: Number of scale infested leaves, shoots per five tender shoots from each of the four directions of the selected tree should be counted
- Borers: Count the number of young and grown up larvae on each plant and record.

For diseases:
Whenever scouting, be aware that symptoms of plant disease problems may be caused by any biotic factors such as fungal, bacterial, viral pathogens or abiotic factors such as weather, fertilizers, nutrient deficiencies, pesticides and abiotic soil problems. In many cases, the cause of the symptom is not obvious. Close examination, and laboratory culture and analysis are required for proper diagnosis of the causal agent of disease. Generally fungal diseases cause the obvious symptoms with irregular growth, pattern & colour (except viruses), however abiotic problems cause regular, uniform symptoms. Pathogen presence (signs) on the symptoms can also be observed like fungal growth, bacterial ooze etc. Specific and characteristic symptoms of the important plant diseases are given in description of diseases section.

Root sampling: Always check plants that appear unhealthy. If there are no obvious symptoms on plants, examine plants randomly and look for lesions or rots on roots and stems. Observe the signs of the causal organism (fungal growth or ooze). It is often necessary to wash the roots with water to examine them properly. If the roots are well developed, cut them to examine the roots for internal infections (discolouration & signs). Count the total number
of roots damaged/infested/infected due to rot should be counted and incidence should be recorded.

**Leaf sampling:** Examine all leaves of each plant for lesions. Leaf diseases cause most damage during the seedling and flowering stages of plant growth. Observe for the symptoms and signs on the infected plant parts. Determine the percent area of leaf infection by counting the number of leaves (leaf area diameter)/plant infected due to disease and incidence should be recorded.

**Stem, flowers and fruits sampling:** Carefully examine the stem, flowers and fruits of plants for symptoms and signs of fungal or bacterial diseases. The stem, flower and fruits should be split or taken apart and examined for discoloration caused by fungi and bacteria. Count the number of stems, flowers and fruits infected due to disease and percent disease incidence should be recorded.

**C. Surveillance through pheromone trap catches:**

Fruit fly traps @ 4-5 traps/acre have to be installed. Traps for each species shall be separated by a distance of >75 feet in the vicinity of the plantations. Fix the traps to the supporting pole at middle of the plant canopy. Change of lures should be made at 2-3 week interval (regular interval). During each week of surveillance, the number of moths/trap should be counted and recorded. The trapped moths should be removed and destroyed after each recording.

**D. Yellow pan water/sticky traps:**

Set up yellow pan water trap/sticky traps 15 cm above the canopy for monitoring aphids and whitefly @ 4-5 traps/acre. Locally available empty tins can be painted yellow and coated with grease/Vaseline/castor oil on outer surface may also be used.

**E. Light trap:**

Set up light traps @ 1 trap/acre 15 cm above the crop canopy for monitoring and mass trapping of nocturnal insects. Light traps with exit option for natural enemies of smaller size should be installed and operated around the dusk time (6 pm to 10 pm).

**F. Nematode extraction:**

Collect 100 to 300 cm³ (200-300 g) representative soil sample. Mix soil sample and pass through a coarse sieve to remove small pieces of stones, roots, etc. Take a 600 cc subsample of soil, pack lightly into a beaker uniformly. Place soil in one of the buckets or pans half filled with water. Mix soil and water by stirring with paddle; allow to stand until water almost stops swirling. Pour all but heavy sediment through 20-mesh sieve into second bucket; discard residue in first bucket; discard material caught on sieve. Stir material in second bucket; allow to stand until water almost stops swirling. Pour all but heavy sediment through 60 mesh sieve to collect cysts into first bucket; discard residue in second bucket. Stir material in first bucket; allow to stand until water almost stops swirling. Pour all but heavy sediment through 325-mesh sieve into second bucket; discard residue in first bucket. Backwash material caught on 325-mesh sieve (which includes small to mid-sized nematodes and silty material) into 250-ml beaker. More than 90% of the live nematodes are recovered in the first 5-8 mm of water drawn from the rubber tubing and the sample is placed in a shallow dish for examination.
III. ECOLOGICAL ENGINEERING FOR PEST MANAGEMENT

Ecological engineering for pest management has recently emerged as a paradigm for considering pest management approaches that rely on the use of cultural techniques to effect habitat manipulation and to enhance biological control. Ecological engineering for pest management is based on informed ecological knowledge rather than high technology approaches such as synthetic pesticides and genetically engineered crops (Gurr et al. 2004 a, b).

Ecological Engineering for Pest Management – Below Ground:

There is a growing realization that soil borne, seed and seedling borne diseases can be managed with microbial interventions, besides choosing appropriate plant varieties. The following activities increase the beneficial microbial population and enhance soil fertility.

- Crop rotations with leguminous plants which enhance nitrogen content.
- Keep soils covered year-round with living vegetation and/or crop residue.
- Add organic matter in the form of farm yard manure (FYM), vermicompost, crop residue which enhance below ground biodiversity of beneficial microbes and insects.
- Application of balanced dose of nutrients using biofertilizers based on soil test report.
- Application of biofertilizers with special focus on mycorrhiza and plant growth promoting rhizobia (PGPR)
- Application of *Trichoderma harzianum/viride* and *Pseudomonas fluorescens* for treatment of seed/seedling/planting materials in the nurseries and plantation (if commercial products are used, check for label claim. However, biopesticides produced by farmers for own consumption in their fields, registration is not required).

Ecological Engineering for Pest Management – Above Ground:

Natural enemies play a very significant role in control of foliar insect pests. Natural enemy diversity contributes significantly to management of insect pests both below and above ground.

**Natural enemies may require:**

1. Food in the form of pollen and nectar.
2. Shelter, overwintering sites and moderate microclimate etc.
3. Alternate hosts when primary hosts are not present.

**In order to attract natural enemies following activities should be practiced:**

- Raise the flowering plants / compatible cash crops along the plantation border by arranging shorter plants towards main crop and taller plants towards the border to attract natural enemies as well as to avoid immigrating pest population
- Grow flowering plants on the internal bunds inside the plantation
- Not to uproot weed plants those are growing naturally such as *Tridax procumbens*, *Ageratum* sp, *Alternanthera* sp etc. which act as nectar source for natural enemies
- Not to apply broad spectrum chemical pesticides, when the P: D ratio is favourable. The plant compensation ability should also be considered before applying chemical pesticides.
- Reduce tillage intensity so that hibernating natural enemies can be saved.
- Select and plant appropriate companion plants which could be trap crops and pest repellent crops. The trap crops and pest repellent crops will also recruit natural enemies as their flowers provide nectar and the plants provide suitable microclimate.

Due to enhancement of biodiversity by the flowering plants, parasitoids and predators (natural enemies) number also will increase due to availability of nectar, pollen and insects etc. The major predators are a wide variety of spiders, ladybird beetles, long horned grasshoppers, lacewing, earwigs, etc.
Plants Suitable for Ecological Engineering for Pest Management

Attractant plants

- Alfalfa
- Cowpea
- Carrot
- Sunflower
- Buckwheat
- French bean
- Mustard
- Cosmos
- Anise
- Caraway
- Dill
- Parsley
- White Clover
- Tansy
- Yarrow
The flowering plants suggested under Ecological Engineering for pest management strategy are known as attractant plants to the natural enemies of the selected pests. The information is based on published research literature, however, the actual selection of flowering plants could be based on availability, agro-climatic conditions and soil types.
Biodiversity of natural enemies observed in Ecological Engineering field at NIPHM

Biodiversity of natural enemies: Parasitoids

Biodiversity of natural enemies: Predators

Biodiversity of natural enemies: Spiders
## IV. CROP STAGE-WISE IPM

<table>
<thead>
<tr>
<th>Management</th>
<th>Activity</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pre-planting</strong>*</td>
<td><strong>Common cultural practices:</strong></td>
</tr>
</tbody>
</table>
| | • Deep ploughing of fields during summer to control nematodes population and weeds.  
  • Soil solarization  
  • Timely sowing should be done.  
  • Field sanitation.  
  • Destroy alternate host plants  
  • Plant tall border crops like maize, sorghum or millet to reduce whitefly and aphid population.  
  • Crop rotation with non-host crops  
  • Adopt ecological engineering by growing attractant, repellent, and trap crops around the field bunds. |
| **Nutrients** | • Papaya plant needs heavy doses of manures and fertilizers. Apart from the basal dose of manures fertilizers are also required.  
  • Nutrient should be applied on the basis of soil test values and recommendation for the particular agro-ecological region.  
  • Papaya seedlings are planted in pits of 60 x 60 x 60 cm size.  
  • The pits are dug in summer about a fortnight before planting.  
  • The pits are filled with top soil along with 20 Kg of FYM, 1 Kg neem cake and 1 Kg bone meal.  
  • Application of 200 g N/pit is optimum for fruit yield but papain yield increases with increase in N up to 300 g/pit. |
| **Weeds** | • Plough the field before planting to destroy existing weeds. |
| **Soil and seed borne pathogens, nematodes** | **Cultural control:** |
| | • Intercropping of marigold reduces nematode population  
  • Nursery should be raised in nematode free sites or fumigated or solarized beds  
  • Application of decomposed poultry manure @ 200 g / sq. m  
  • Biological control:  
  • Apply neem cake @ 100 Kg/acre at the time of transplanting for reducing nematodes and borer damage. |
| **Sowing/ seedling*** | **Nutrients** |
| | • Planting is done in pits already filled with top soil and farm yard manure.  
  • Apply 20 g each of *Azospirillum* and *Phosphobacterium* per plant at planting and again six months after planting. |
| **Weeds** | • Use weed free seedlings for planting.  
  • Remove existing weeds manually in and around the pits at the time of planting.  
  • Mulching with organic materials around the pits.  
  • To suppress the weeds between rows, intercropping of leguminous crops after non-leguminous ones, shallow rooted crops after deep rooted ones are beneficial. No intercrops are taken after the onset of flowering stage.  
  • Use straw or plastic mulch to avoid weed growth and to maintain soil moisture for longer period in between the rows. |
### Soil borne diseases

**Cultural control:**
- Use seedlings raised in insect proof conditions.
- Sow 4-5 seeds/bag then retain 3 seedlings.
- Use 2 month old seedlings for transplanting
- Papaya don't withstand water logging, hence well drained upland fields should be selected for cultivation.
- Under drip, ring method should be followed.
- Wind breaks should be grown to protect from strong wind also save tree from cold damage

**Mechanical control:**
- Remove and destroy virus infected seedlings/plants.

**Biological control**
- Apply 5% neem seed kernel extract (NSKE) or groundnut oil @ 1-2% on to the plants to manage the vector population.

### Nematodes and insects

**Cultural control:**
- Use resistant/tolerant varieties.
- Sowing should be completed within recommended periods.
- Intercropping with sunnhemp or marigold or daincha.

**Biological control**
- Use mahua (*Madhuca longifolia*), castor, neem and karanj (*Pongamia pinnata*) cakes, biogas sludge applied at 1.0 t/acre during pit preparation.
- Apply 2 tons of FYM enriched with *Pochonia chlamydosporia* and *Paecilomyces lilacinus* before sowing, along with 100-200 Kg of neem or pongamia cake.
- Apply neem based products (Neemagon, Bioneem, Neemraj etc.) for controlling this pest.

*Application of *Trichoderma harzianum/viride* and *Pseudomonas fluorescens* for treatment of seed/seedling/planting materials in the nurseries and plantation (if commercial products are used, check for label claim. However, biopesticides produced by farmers for own consumption in their fields, registration is not required).*

### Vegetative stage

**Common cultural practices:**
- Collect and destroy crop debris.
- Provide irrigation at critical stages of the crop.
- Avoid water stress and water stagnation conditions.

**Common mechanical practices:**
- Collection and destruction of eggs and larvae.
- Collect and destroy disease infected and insect infested plant parts.
- Handpick the gregarious caterpillars and the cocoons which are found on stem and destroy them in kerosene mixed water.
  - Use yellow sticky traps for aphids and whitefly @ 4-5 traps/acre.
  - Use light trap @ 1/acre and operate between 6 pm and 10 pm.
- Install pheromone traps @ 4-5 traps/acre for monitoring adult moths activity (replace the lures with fresh lures after every 2-3 weeks)
- Erecting of bird perches @ 20/acre for encouraging predatory birds such as King crow, common mynah etc.
- Set up bonfire during evening hours between 7-8 pm

**Common biological practices:**
- Conserve natural enemies through ecological engineering.
- Augmentative release of natural enemies.
- Enhance parasitic activity by avoiding chemical spray, when 1-2 larval parasitoids are observed.
### Nutrients
- Apply 50 g each of N, P and K per plant at bi-monthly intervals from the third month of planting.
- The application of 25% N in organic form and 75% N in inorganic form along with green manure crops is beneficial.
- Apply 20 g each of *Azospirillum* and *Phosphobacterium* per plant again at six months after planting.

### Weeds
- Inter cultivation is recommended during the first year to check weed growth. Weeding should be done on regular basis especially around the plants.
- Earthing up is done before or after the onset of monsoon to avoid water-logging and also to help the plants to stand erect.
- In subsequent seasons to suppress the weeds between rows, intercropping of leguminous crops after non-leguminous ones, shallow rooted crops after deep rooted ones are beneficial. No intercrops are taken after the onset of flowering stage.
- Use straw or plastic mulch to avoid weed growth and to maintain soil moisture for longer period.

### Mealybug
- **Cultural control:**
  - Removal of weeds and alternate host plants like Hibiscus, bhindi, custard apple, guava etc and in and nearby vineyards throughout the year.
  - Application of sticky bands (or) alkathene sheet (or) a band of insecticide on arms (or) on main stem to prevent the movement of crawlers.
  - Prevention of the movement of ants and destruction of already existing colonies

### Aphids**
- **Cultural control:**
  - Check transplants for aphids before planting.
  - Reflective mulches such as silver colored plastic can deter aphids from feeding on plants.
  - Sturdy plants can be sprayed with a strong jet of water to knock aphids from leaves.

### Whitefly**
- **Cultural control:**
  - Water sprays may also be useful in dislodging adults.
  - A small, hand-held, battery-operated vacuum cleaner has also been recommended for vacuuming adults off leaves. Vacuum in the early morning or other times when it is cool and whiteflies are sluggish. Kill insects by placing the vacuum bag in a plastic bag and freezing it overnight. Contents may be disposed of the next day. Fumigating with a small petrol soaked cotton ball.

### Stem borer**
- **Cultural control:**
  - Pierce the infested plants with a sharp needle or knife to kill the caterpillar in the stem.

### Grasshopper
- **Cultural control:**
  - Removal of weeds and alternate host plants such as *Hibiscus*, bhindi, custard apple, guava etc.
### Foot rot
- Follow common cultural, mechanical and biological practices (See page no. 13, 14)
- For resistant/tolerant varieties consult nearest KVks/ICAR Institutes/SAUs

**Cultural control:**
- The crop should be irrigated by adopting the ring method of irrigation so that the water does not come in direct contact with the stem.
- Avoid water logging.

### Anthracnose
- Follow common cultural, mechanical and biological practices (See page no. 13, 14)
- For resistant/tolerant varieties consult nearest KVks/ICAR Institutes/SAUs

**Cultural control:**
- Diseased leaves, twigs, gall midge infected leaves and fruits, should be collected and burnt.

**Mechanical control:**
- Covering the fruits on trees, 15 days prior to harvest with news or brown paper bags.

### Powdery mildew**
- Follow common cultural, mechanical and biological practices (See page no. 13, 14)
- For resistant/tolerant varieties consult nearest KVks/ICAR Institutes/SAUs

**Cultural control:**
- The crop should be irrigated by adopting the ring method of irrigation so that the water does not come in direct contact with the stem.
- Keep proper spacing during sowing.

**Mechanical control:**
- Prune diseased leaves to reduce primary inoculum load.

**Chemical control:**
- Thiophanate methyl 70% WP @ 286 g in 300-400 l of water/acre (thiophanate methyl 70% WP @ 0.1% along with sticker @ 0.05%)

### Papaya mosaic virus
- Follow common cultural, mechanical and biological practices (See page no. 13, 14)
- For resistant/tolerant varieties consult nearest KVks/ICAR Institutes/SAUs

**Cultural control:**
- Good field sanitation such as removal and destruction of affected plants
- Losses can be minimized by controlling the population of aphid.

### Papaya leaf curl virus**
- Follow common cultural, mechanical and biological practices (See page no. 13, 14)
- For resistant/tolerant varieties consult nearest KVks/ICAR Institutes/SAUs

**Cultural control:**
- Uproot the virus affected plants & control whitefly vector.
- Avoid growing tomato, tobacco near papaya.
- Removal and destruction of the affected plants is the only control measure to reduce the spread of the disease.
- The field should be kept weed free. Tobacco, tomato, sunnhemp, cape gooseberry, chilli, petunia, Datura stramonium, Zinnia elegans etc. should not be grown nearby papaya field.

### Papaya ring spot virus
- Follow common cultural, mechanical and biological practices (See page no. 13, 14)
- For resistant/tolerant varieties consult nearest KVks/ICAR Institutes/SAUs

**Cultural control:**
- Early detection of infected plants and prompt removal can check the spread of the disease.
- Rogue out infected plants of papaya as early as possible to avoid further infection within the field.
- Avoid taking mixed crop of tobacco, chilli, Zinnia, tomato and gooseberry in papaya field or nearby.

**Mechanical control:**
- Use of yellow sticky trap for control of aphid vector.

### Flowering/Maturity stage

#### Nutrients
- Apply recommended micronutrients, if symptoms are observed.
- Micro-nutrients viz., ZnSO₄ (0.5%) and H₂BO₃ (0.1%) are sprayed in order to increase growth and yield characters.

#### Weeds
- Remove weeds around the plants.
- Continue the use of straw or plastic mulch to avoid weed growth and to maintain soil moisture for longer period.
**Fruit fly**

- Follow common cultural, mechanical and biological practices (See page no. 13, 14)

  **Cultural control:**
  - Prior to harvest, collect and dispose off infested and fallen fruits to prevent further multiplication and carry-over of population.
  - Ploughing of papaya plantation during November-December to expose pupae to sun’s heat which kills them.
  - If infestation is heavy, do bait splash on the trunk only, once or twice at weekly interval is recommended. To prepare bait splash, mix 100 g of jaggery in one litre of water and add 1 ml of killing agents by using an old broom.
  - Managing fruit flies also reduces anthracnose disease and prevents late fruit fall.

  **Physical control:**
  - Hot water treatment of fruit at 48 ± 1 °C for 45 min.
  - Male annihilation technique: Set up fly trap using methyl eugenol. Prepare methyl eugenol 1 ml/L of water + 1 ml of malathion solution. Take 10 ml of this mixture per trap and keep them at 25 different places in one ha between 6 and 8 am. Collect and destroy the adult flies.

**Scale insects**

- Follow common cultural, mechanical and biological practices (See page no. 13, 14)

  **Mechanical control:**
  - Prune heavily infested plant parts to open the tree canopy and destroy’ them immediately and preferably during summer.
  - These should be placed in a pit constructed on one corner of the field. Allow branches and twigs to dry until the parasitoids escape.
  - Burn the remaining debris.
  - Removal of attendant ants may permit natural enemies to control the insect.

**Grey weevil**

- Follow common cultural, mechanical and biological practices (See page no. 13, 14)

  **Cultural control:**
  - Collection and destruction of infested and fallen fruits at weekly interval till harvesting is completed.
  - Destroy all left over seeds in the field and also in the processing industries.

**Other insect pests & disease**

- Same as in vegetative stage.

**Birds**

- Mechanical control:
  - Install bird scarers or metallic ribbons to ward off the birds.

**Post-harvest**

<table>
<thead>
<tr>
<th>Anthracnose, Stem end rot, Aspergillus rot, Rhizopus rot, Fruit rot, Phomopsis rot</th>
<th><strong>Cultural control:</strong></th>
</tr>
</thead>
</table>
| | • Avoid harvesting of immature fruits
| | • Cool fruits immediately after harvest and store in well ventilated containers.
| | • The disease can be checked by sorting the fruit at 100 °C or below but the rot appears after 2-3 days when such fruits are brought back to 20 °C or above.

  **Physical control:**
  - Hot water treatment at 49 ºC for 20 min.

  **Botanical control:**
  - Postharvest dip treatment of fruits with botanical fungicides could also control the diseases during storage.

Note: Pesticides dosage use is based on high volume sprayer. The recommended chemicals given are as per CIBRC list updated on 31.10.2014.

**Pests of regional significance**
V. INSECTICIDE RESISTANCE AND ITS MANAGEMENT

Insecticide resistance: Resistance to insecticides may be defined as ‘a heritable change in the sensitivity of a pest population that is reflected in the repeated failure of a product to achieve the expected level of control when used according to the label recommendation for that pest species’ (IRAC). Cross-resistance occurs when resistance to one insecticide confers resistance to another insecticide, even where the insect has not been exposed to the latter product.

Causes of resistance development: The causes and rate at which insecticide resistance develops depend on several factors, including the initial frequency of resistance alleles present in the population, how rapidly the insects reproduce, the insects’ level of resistance, the migration and host range of the insects, the insecticide’s persistence and specificity, and the rate, timing and number of applications of insecticide made. For instance, insect pests that survive in large populations and breed quickly are at greater advantage of evolving insecticide, especially when insecticides are misused or over-used.

General strategy for insecticide resistance management: The best strategy to avoid insecticide resistance is prevention and including insecticide resistance management tactics as part of a larger integrated pest management (IPM) approach.

1) Monitor pests: Monitor insect population development in fields to determine if and when control measures are warranted. Monitor and consider natural enemies when making control decisions. After treatment, continue monitoring to assess pest populations and their control.

2) Focus on AESA. Insecticides should be used only as a last resort when all other non-chemical management options are exhausted and P: D ratio is above 2: 1. Apply biopesticides/chemical insecticides judiciously after observing unfavourable P: D ratio and when the pests are in most vulnerable life stage. Use application rates and intervals as per label claim.

3) Ecological engineering for pest management: Flowering plants that attract natural enemies as well as plants that repel pests can be grown as border/intercrop.

4) Take an integrated approach to managing pests. Use as many different control measures as possible viz., cultural, mechanical, physical, biological etc. Select insecticides with care and consider the impact on future pest populations and the environment. Avoid broad-spectrum insecticides when a narrow-spectrum or more specific insecticide will work. More preference should be given to green labeled insecticides.

5) Mix and apply carefully. While applying insecticides care should be taken for proper application of insecticides in terms of dose, volume, timing, coverage, application techniques as per label claim.

6) Alternate different insecticide classes. Avoid the repeated use of the same insecticide, insecticides in the same chemical class, or insecticides in different classes with same mode of action and rotate/alternate insecticide classes and modes of action.

7) Preserve susceptible genes. Preserve susceptible individuals within the target population by providing unsprayed areas within treated fields, adjacent “refuge” fields, or habitat attractions within a treated field that facilitate immigration. These susceptible individuals may outcompete and interbreed with resistant individuals, diluting the resistant genes and therefore the impact of resistance.
### VI. NUTRITIONAL DEFICIENCIES

<table>
<thead>
<tr>
<th>Nutrients</th>
<th>Figure</th>
</tr>
</thead>
</table>
| **Nitrogen:** Nitrogen deficiency causes slow growth and older leaves become paler with reduced leaf area and rate of leaf production. Leaf petioles short, thin and compressed.  
**Correction Measure:** Foliar spray of urea @2%. |
| **Phosphorus:** The deficiency of P causes complete cessation of elongation, older leaves becoming increasingly irregularly necrotic, leaf production is reduced, and marginal choloruses and premature death are caused. P deficiency causes a blue or dark green coloration of leaves.  
**Correction Measure:** Soil application of phosphatic fertilizer as per the recommendation. |
| **Potassium:** Deficiency of potassium causes marked reduction in growth, leaves profusely smaller, leaf margins necrosis and premature yellowing of plant. Purplish brown patches appear at the base of the petioles. Fruits are badly shaped, poorly filled and unsuitable for marketing.  
**Correction Measure:** Foliar spray of KCl @2%. |
| **Magnesium:** Symptoms show green banding around the margin and next to the midrib. Leaves turn yellowish brown margin. Plant height reduced marginal yellowing of leaf margin extends towards the midrib. Purplish mottling of leaf petiole and malformation of leaves.  
**Correction Measure:** Foliar spray of MgSO₄ @1-2%. |
| **Sulphur:** Deficiency causes chlorosis and delaying of green colour in newly emerging leaves, reduced plant growth and reduced leaf size. The leaf blades become very soft and tear easily.  
**Correction Measure:** Foliar spray of MgSO₄@1%. |
**Boron:** Distortion of newer leaves and the growing point dies. Leaves show chlorotic symptom with inward cupping with stunted growth. Bushy appearance of shoot.

**Correction Measure:** Soil application of borax @ 2-3 g/plant.

---

**Manganese:** Marginal chlorosis of young leaves, which later turn brown. Fruits with raised spots which are dark brown or black in colour. Leaves give striped appearance from the edges.

**Correction Measure:** Foliar spray of MnSO₄ @1-2%.

---

---

**VII. COMMON WEEDS**

1. **Carrot grass:** *Parthenium hysterophorus* (L.) Scop. (Asteraceae)
2. **Coat buttons:** *Tridax procumbens* L. (Asteraceae)
3. **Yellow spider flower:** *Cleome viscosa* L. (Capparidaceae)
4. **Asthma herb/Spurge:** *Euphorbia hirta* L. (Euphorbiaceae)
5. **Cock’s comb:** *Celosia argentea* L. (Amaranthaceae)
6. **Pigweed:** *Amaranthus viridis* Hook. F. (Amaranthaceae)
7. Goat weed: *Ageratum conyzoides* L. (Asteraceae)

8. Large crabgrass: *Digitaria sanguinalis* L. (Scop.) (Poaceae)

9. Yellow foxtail: *Setaria glauca* (L.) P. Beauv. (Poaceae)

12. Purple nutsedge: *Cyperus rotundus* L. (Cyperaceae)

13. Flat sedge: *Cyperus iria* L. (Cyperaceae)

14. Umbrella sedge: *Cyperus difformis* L. (Cyperaceae)
VIII. DESCRIPTION OF INSECT AND NEMATODE PESTS

1) Papaya mealybug:

**Biology:**

**Egg:** Females usually lay 100 to 600 eggs. Eggs are greenish yellow and are laid in an ovisac sac that is three to four times the body length and entirely covered with white wax. Egg-laying usually continuous over a period of one to two weeks.

**Nymph:** Eggs hatch in about 10 days, and nymphs or crawlers begin to actively search for feeding sites.

**Adult:** The adult female is yellow, approximately 3 mm long and 1.4 mm wide and is covered with a white waxy coating. Adult males are pink, especially during the pre-pupal and pupal stages, but appear yellow in the first and second instars. Adult males are approximately 1.0 mm long, with an elongate oval body that is widest at the thorax (0.3 mm).

**Life cycle:**

![Life cycle of Papaya mealybug](image)

**Damage symptoms:**
- Initially the affected portion will be chlorotic, later changed to brown and dry away.
- These bug excrete honey dew and as a result infested portion becomes shiny and moist and to this, secondary infection by sooty fungus, *Capnodium* growth results in black covering the affected parts.
- Papaya mealybug is polyphagous pest. Symptoms can be observed on leaves, stems and fruits as clusters of cotton like masses.

**Natural enemies of papaya mealybug:**

**Parasitoids:** Acerophagus papaya, Phygidium spp., Leptomastix menciona, Anagurus leckii, etc.

**Predators:** Spalgis epius, Cryptolaemus montrouzieri, Rodolia fumida etc.

The entomogenous fungus Beauveria bassiana.

*For management refer to page number 15.*
2) Whitefly:

**Biology:**

**Egg:** The females mostly lay eggs near the veins on the underside of leaves. Each female can lay about 300 eggs in its lifetime. Eggs are small (about 0.25 mm), pear-shaped, and vertically attached to the leaf surface through a pedicel. Newly laid eggs are white and later turn brown.

**Nymph:** Upon hatching, the first instar larva (nymph) moves on the leaf surface to locate a suitable feeding site. Hence, it is commonly known as a “crawler”. It then inserts its piercing and sucking mouthpart and begins sucking the plant sap from the phloem. Adults emerge from puparium through a T-shaped slit, leaving behind empty pupal cases or exuviae.

**Adult:** The whitefly adult is a soft-bodied, and moth-like fly. The wings are covered with powdery wax and the body is light yellow in color. The wings are held over the body like a tent. The adult males are slightly smaller in size than the females. Adults live from one to three weeks.

**Life cycle:**

<table>
<thead>
<tr>
<th>Stage</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eggs</td>
<td>2-8 days</td>
</tr>
<tr>
<td>Nymphs</td>
<td>9-19 days</td>
</tr>
<tr>
<td>Pupa</td>
<td>3-30 days</td>
</tr>
<tr>
<td>Adults</td>
<td>15-30 days</td>
</tr>
</tbody>
</table>

**Damage symptoms**

- Both the adults and nymphs suck the plant sap and reduce the vigor of the plant. In severe infestations, the leaves turn yellow and drop off. When the populations are high they secrete large quantities of honeydew, which favors the growth of sooty mould on leaf surfaces and reduces the photosynthetic efficiency of the plants.

**Natural enemies of whitefly:**

**Parasitoids:** Encarsia formosa, Eretmocerus spp., Chrysocharis pentheus etc.

**Predators:** Dicyphus hesperus, lacewing, ladybird beetle, big-eyed bugs (Geocoris sp) etc.

*For management refer to page number 15.

3) Aphid:

**Biology:**

**Egg:** Eggs are very tiny, shiny-black, and are found in the crevices of bud, stems, and barks of the plant. Aphids usually do not lay eggs in warm parts of the world.

**Nymph:** Nymphs (immature stages) are young aphids, they look like the wingless adults but are smaller. They become adults within 7 to 10 days.

**Adult:** Adults are small, 1 to 4 mm long, soft-bodied insects with two long antennae that resemble horns. Most aphids have two short cornicles (horns) towards the rear of the body.
AESA based IPM – Papaya

**Life cycle:**

1. **Eggs**
   - 3-5 days

2. **Nymphs**
   - 1-2 days

3. **Adults**
   - 5-10 days

**Aphid, Aphis gossypii**

**Damage symptoms:**
- Infesting tender shoots and under surface of the leaves.
- Curling and crinkling of leaves
- Stunted growth
- Development of black sooty mould due to the excretion of honeydew

**Natural enemies of aphid:**

**Parasitoids:** Aphidius colemani, Aphelinus sp etc.

**Predators:** Fire ant, robber flies, big-eyed bug (Geocoris sp), earwig, ground beetle, Cecidomyiid fly, dragonfly, praying mantis, lacewing, ladybird beetle, spider etc.

*For management refer to page number 15.*

**4) Fruit fly:**

**Biology:**

**Egg:** Female flies insert eggs under the skin of fruit in clusters of 10 to 50 about 1/25 to 1/8 inch below the fruit surface. The eggs measure about 1/25 by 1/250 inch and are white, elongate, and elliptical. They hatch in 1-1/2 days.

**Larva:** The white larva is legless, and resembles an elongated cone. The mouth is at the pointed end of the body. There are 3 larval stages, or instars. The third instar is about 2/5 inch long. The entire larval stage lasts for 11-15 days.

**Pupa:** When mature, larvae drop to the ground and pupate in the soil. The puparium is yellowish-brown and seed-like. Adults emerge in about 10 days.

**Adult:** Generally, the abdomen has two horizontal black stripes and a longitudinal median stripe extending from the base of the third segment to the apex of the abdomen. These markings may form a “T” shaped pattern, but the pattern varies considerably. Females begin to lay eggs about 8 days after emergence from the puparium. Under optimum conditions, a female can lay more than 3,000 eggs during her lifetime, but under field conditions approximately 1,200 to 1,500 eggs per female is considered to be the usual production. Ripe fruit are preferred for egg laying, but immature ones may be also attacked.
Life cycle:

Damage symptoms:

- The female punctures outer wall of mature fruits with the help of its pointed ovipositor and insert eggs in small clusters inside mesocarp of mature fruits.
- On hatching, the maggots feed on fruit pulp and the infested fruits start rotting due to further secondary infection

Natural enemies of fruit fly:

Parasitoids: Opius fletcheri, Fopius arisanus, Diachasmimorpha kraussi etc.

Predator: Ants

*For management refer to page number 17.

5) Grasshopper:

Biology:

Egg: Adult females lay eggs along the midrib and lateral veins of the leaves. The egg period is 4 to 11 days.

Nymph: The nymphs resemble the adults, but lack wings. Instead, they have slightly extended wing pads. They are pale green in color. They tend to move sideways when disturbed. The nymphal period varies from one to four weeks depending on the temperature.

Adult: The adults are wedge-shaped, pale green insects. They have fully developed wings with a prominent black spot on each forewing. The adults may live for one to two months.

Damage symptoms:

- Both nymphs and adults suck the sap from the lower leaf surfaces through their piercing and sucking mouthparts. While sucking the plant sap, they also inject toxic saliva into the plant tissues, which leads to yellowing. When several insects suck the sap from the same leaf, yellow spots appear on the leaves, followed by crinkling, curling, bronzing, and drying, or “hopper burn”.

Natural enemies of grass hopper:

Parasitoids: Lymaenon empoascae (egg), Anagrus flaveolus, Stethynium triclavatum etc.

Predators: Predatory birds, praying mantis etc.

*For management refer to page number 15.
6) Reniform nematode:

Biology:
- The predominant reniform species found on papayas in most parts of the world is *R. reniformis*.
- Many commonly cultivated crops as well as weeds are hosts of the reniform nematodes.
- Because of their small size, they do not travel distances of more than a few inches in their lifetime.
- Juveniles that hatch from eggs are less than 500 µm long.
- After undergoing several molts, female juveniles become young adults and penetrate the root cortex and become sedentary.
- The portion of the body that remains outside the root enlarges and becomes kidney-shaped, hence the name “reniform.” After maturation the female secretes a gelatinous substance around her body (the sand-like bodies referred to above) into which she lays about 100 eggs.
- A complete life cycle is possible in about 25 days. The reniform nematode feeds near the phloem in papaya roots inducing the formation of giant cells.
- These are centers of high metabolic activity that compete with other parts of the plant for food and nutrients.
- The nematode also may feed in the root cortex and cause mechanical breakdown of the cortical cells, thus providing suitable sites for attack by fungi.

![Life cycle of reniform nematode](http://plnemweb.ucdavis.edu/nemaplex/Taxadata/G116S2.HTM)

Symptoms:
- Above-ground symptoms of plants infected by the reniform nematode are similar to those associated with one or more of the following conditions: 1) lack of proper nutrients, 2) chronic moisture stress, and/or 3) poor soil aeration.
- The above-ground symptoms appear as moderate to severe leaf chlorosis and plant stunting. Some wilting may occur during periods of peak transpirational stress on the plant.
- Below ground symptoms are not readily detectable by the untrained observer. However, reniform nematode presence on the roots may be observed with the aid of a 10x hand lens.
- The small sand-like bodies which remain attached, after the root system is carefully washed, are eggmasses of the nematode.
- Fruits produced are smaller than normal and may be slightly insipid.

![Various life stages of reniform nematode](http://entnemdept.ufl.edu/creatures/nematode/r_reniformis.htm)

*For management refer to page number 14.*
7) Root-knot nematode:

**Biology:**
- Most species of plant parasitic nematodes have a relatively simple life cycle consisting of the egg, four larval stages and the adult male and female.
- Development of the first stage larvae occurs within the egg where the first molt occurs. Second stage larvae hatch from eggs to find and infect plant roots or in some cases foliar tissues.
- Under suitable environmental conditions, the eggs hatch and new larvae emerge to complete the life cycle within 4 to 8 weeks depending on temperature.
- Nematode development is generally most rapid within an optimal soil temperature range of 70 to 80°F.

**Life cycle:**

<table>
<thead>
<tr>
<th>Stage</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Egg</td>
<td>4-6 days</td>
</tr>
<tr>
<td>Larvae [Infected J2 juveniles]</td>
<td>12-16 days</td>
</tr>
<tr>
<td>Adults Male (longer)</td>
<td>16-22 days</td>
</tr>
<tr>
<td>Adults Female (bulged)</td>
<td>25-30 days</td>
</tr>
</tbody>
</table>

**Damage symptoms:**
- Infected plants in patches in the field
- Formation of galls on host root system is the primary symptom
- Roots branch profusely starting from the gall tissue causing a ‘beard root’ symptom
- Infected roots become knobby and knotty
- In severely infected plants the root system is reduced and the rootlets are almost completely absent. The roots are seriously hampered in their function of uptake and transport of water and nutrients
- Plants wilt during the hot part of day, especially under dry conditions and are often stunted
- Nematode infection predisposes plants to fungal and bacterial root pathogens

**Survival and spread:**

**Primary:** Egg masses in infected plant debris and soil or collateral and other hosts like Solonaceous, Malvaceous and Leguminaceous plants act as sources of inoculums.

**Secondary:** Autonomous second stage juveniles that may also be water dispersed.

**Favourable conditions:** Loamy light soils.

*For management refer to page number 14.*

7. Preying mantis
8. Predatory mite
9. Hover fly
10. Black drongo
11. Common mynah

## IX. DESCRIPTION OF DISEASES

### 1) Foot rot of papaya:

#### Disease symptoms:
- It is characterized by the appearance of water-soaked patches on the stem near the ground level.
- These patches enlarge rapidly and girdle the stem, causing rotting of the tissues, which then turn dark brown or black. Such affected plants withstand strong wind and topple over and die.
- If the disease attack is mild, only one side of the stem rots and the plants remain stunted.
- Fruit if formed are shrunken and malformed. Gradually the plant dies.

#### Survival and spread:
- Resting spore, oospore, germinate and release zoospores which along with irrigation water spread throughout the field.

#### Favourable conditions:
- High relative humidity and rainy condition favors the severe disease development in sick soil

*For management refer to page number 16.

### 2) Anthracnose:

#### Disease symptoms:
- Disease occurs both in field and in storage conditions.
- The spots on fruits first appear as brown superficial discolouration of the skin which develops into circular, slightly sunken areas and 1 to 3 cm in diam.
- Gradually the lesions coalesce and sparse mycelia growth appears on the margins of the spots.
- Under humid conditions, an encrustation of salmon pink spores is released.
- Infection at early stages of fruit results in mummification and deformation.
- Lesions develop more slowly on the immature fruits than on the mature fruits.

#### Survival and spread:
- The disease is spread through wind-borne conidia.
- Conidia are also spread by rain splashes.

#### Favourable conditions:
- High relative humidity coupled with higher temperatures favour disease development. Maximum disease development takes place at about 26°C under wet weather condition.

*For management refer to page number 16.

1. Anthracnose affected Papaya fruits in field and storage conditions

1: [http://growfoodslowfood.blogspot.in/2012/08/what-is-wrong-with-my-papya.html](http://growfoodslowfood.blogspot.in/2012/08/what-is-wrong-with-my-papya.html)

*For management refer to page number 16.
3) Powdery mildew:

**Disease symptoms:**
- On the undersurface of disease leaves are found patches of whitish powder growth. On upper surfaces, leaves at the infection site show blotches of yellow or pale green usually near vein, surrounded by normally colored tissue.
- Occasionally, fungus may attack the stem of young seedling when grown under reduced light condition.
- The spots enlarge and cover the entire leaf area. Severely infected leaves may become chlorotic and distorted before falling. Affected fruits are small in size and malformed.
- Fungus grow superficially on the undersurface of the leaves with drawing nutrients from the cell of leaf surface by specialized absorbing structure known as haustoria.

**Survival and spread:**
- The powdery mildew fungus overwinters in dormant buds. When conditions are favorable for growth of the fungus in spring, spores are produced, released, and cause new infections.
- Secondary spread of the disease can occur if spores are produced in these new infections.

**Favourable conditions:**
- The development of disease is favour by relative humidity around 80-85% and temperature range of 24-26°C.

![Disease symptoms](image1.png)

*For management refer to page number 16.

4) Papaya ring spot disease:

**Disease symptoms:**
- Infected plant initially shows chlorosis on youngest leaves followed by vein clearing, rugosity and prominent mottling of laminae.
- Malformation and reduction of the lamina which may become extremely filiform.
- Characteristically elongated dark green streak develop on petiole and upper half of the stems, infected fruits show circular concentric rings causes upto 56-60 % yield loss.
- Pathogen belongs to Potyvirus group of Potyviridae family.

**Transmission and favourable conditions:**
- Disease is aphid transmitted and aphids are more active during warmer conditions.
- PRSV is also easily transmitted via mechanical inoculation but there are no confirmed reports of PRSV transmission through seeds.

*For management refer to page number 16.
5) Papaya mosaic disease:

**Disease symptoms:**
- Leaf mosaic and stunting in plant.
- Young seedlings in the greenhouse show vein-clearing and downward cupping of the leaves about 5 days after inoculation.
- A mottle or mosaic develops after 15-20 days.
- Symptoms appear on the young leaves of the plants. The leaves are reduced in size and show blister like patches of dark-green tissue, alternating with yellowish-green lamina.
- The leaf petiole is reduced in length and the top leaves assume an upright position.

**Transmission and favourable conditions:**
- Papaya mosaic diseases is mechanically transmissible viruses associated with other viral disease, from papaya mosaic virus in being aphid-borne and restricted in host range to papaya and cucurbits.

*For management refer to page number 16.

6) Papaya leaf curl disease:

**Disease symptoms:**
- Curling, crinkling and distortion of leaves, reduction of leaf lamina, rolling of leaf margins inward and downward, thickening of veins.
- Leaves become leathery, brittle and distorted. Plants stunted. Affected plants does not produce flowers and fruits.
- Sometimes all the leaves at the top of the plant are affected by these symptoms. In advanced stages of the disease, defoliation takes place and the growth of the plant is arrested.
- PLCV is in the family Geminiviridae. It is not transmitted mechanically.

**Transmission and favourable conditions:**
- The virus can not be transferred mechanical means as in the case of mosaic disease. The virus readily transmitted through grafting and white fly (*Bemisia tabaci*).

*For management refer to page number 16.*
Disease cycles:
1. Foot rot:
   - Sore present in plant debris are source of primary infection
   - Fungus survives in disease plant debris or in soil in form of resting spore
   - Foot rot of papaya
   - Secondary spread of the disease by sexual spore

2. Anthracnose:
   - Resting spores are the source of primary infection
   - Fungus survives in plant debris or in soil for long time
   - Anthracnose of papaya
   - Secondary spread of the disease by means of conidia

3. Powdery mildew:
   - Resting spores are the source of primary infection
   - The powdery mildew fungus overwinters in dormant buds
   - Powdery mildews of Papaya
   - Symptoms on leaves and inflorescence
   - Secondary spread of the disease can occur if spores are produced in these new infections

X. SAFETY MEASURES

A. At the time of harvest:
   - Picking should start when the plants are 11 months of age and continues for 48 months when the plants are 25 ft (7.5 m) high, too tall for further usefulness.
   - The fruits are best packed in single layers and padded to avoid bruising. The latex oozing from the stem may irritate the skin and workers should be required to wear gloves and protective clothing.
   - In the usual papaya plantation, each plant may ripen 2 to 4 fruits per week over the fruiting season. Healthy plants, if well cared for, may average 34 Kg of fruit per plant per year, though individual plants have borne as much as 136 Kg.
   - Home growers may twist the fruit to break the stem, but in commercial operations it is preferable to use a sharp knife to cut the stem and then trim it level with the base of the fruit. However, to expedite harvesting of high fruits, most people should furnish their pickers with a bamboo pole with a rubber suction cup (from the well-known "plumber's helper") at the tip.
   - The fruits must be handled with great care to avoid scratching and leaking of latex which stains the fruit skin.
   - With the cup held against the lower end of the fruit, the pole is thrust upward to snap the stem and the falling fruit is caught by hand. One man can thus gather 363-454 Kg daily.
   - Papaya plants bear well for 2 years and then productivity declines and commercial plantings are generally replaced after 3-4 years. By that time they have attained heights which make harvesting difficult.

Maturity indices:
   - Change of skin color from dark-green to light-green with some yellow at the blossom end (color break). Papayas are usually harvested at color break to ¼ yellow for export or at ½ to ¾ yellow for local markets.
   - Flesh color changes from green to yellow or red (depending on cultivar) as the papayas ripen.
   - A minimum soluble solids of 11.5% is required by the Hawaiian grade standards.
Quality indices:
- Papayas picked ¼ to full yellow taste better than those picked mature - green to ¼ yellow because they do not increase in sweetness after harvest
- Uniformity of size and color; firmness; freedom from defects such as sunburn, skin abrasions, pitting, insect injury, and blotchy coloration; freedom from decay

B. During post-harvest storage:

Post harvest disorders:
1. Physiological and physical disorders:
   - Skin abrasions: Result in blotchy coloration such as green islands (areas of skin that remain green and sunken when the fruit is fully-ripe) and accelerate water loss. Abrasion and puncture injuries are more important than impact injury for papayas.
   - Chilling injury: Symptoms include pitting, blotchy coloration, uneven ripening, skin scald, hard core (hard areas in the flesh around the vascular bundles), water soaking of tissues, and increased susceptibility to decay. Increased alternaria rot was observed in mature-green papayas kept for 4 days at 2°C, 6 days at 5°C, 10 days at 7.5°C, or 14 days at 10°C. Susceptibility to chilling injury varies among cultivars and is greater in mature- green than ripe papayas (10 vs. 17 days at 2°C; 20 vs. 26 days at 7.5°C).
   - Heat injury: Exposure of papayas to temperatures above 30°C (86°F) for longer than 10 days or to temperature-time combinations beyond those needed for decay and/or insect control result in heat injury (uneven ripening, blotchy ripening, poor color, abnormal softening, surface pitting, accelerated decay). Quick cooling to 13°C (55°F) after heat treatments minimizes heat injury.

2. Pathological disorders:
   - Anthracnose: Caused by Colletotrichum gloesporioides, is a major cause of postharvest losses. Latent infections of unripe papayas develop as the fruits ripen. Lesions appear as small, brown, superficial, watersoaked lesions that may enlarge to 2.5 cm (1 inch) or more in diameter.
   - Black stem-end rot: Caused by Phoma caricae-papayae attacks fruit pedicel. After harvest, the disease lesion on fruits appear in the stem area which becomes dark-brown to black. Another stem-end rot is caused by Lasiodiplodia theobromae.
   - Phomopsis rot: Caused by Phomopsis caricae-papayae begins in the stem end or a fruit skin wound and can develop rapidly in ripe fruits; invaded tissue softens and darkens slightly.
   - Phytophthora stem-end rot: Caused by Phytophthora nicotianae var. parasitica begins as water-soaked areas followed by white mycelium that become encrusted.
   - Alternaria rot: Caused by Alternaria alternata follows chilling injury of papayas kept at temperatures below 12°C (54°F).

Control strategies:
1. Careful handling to minimize mechanical injuries
2. Prompt cooling and maintenance of optimum temperature and relative humidity throughout postharvest handling operations
3. Dipping in hot water at 49°C for 20 minutes

Heat treatments for insect control:
1. Hot water treatment: 30 minutes at 42°C followed within 3 minutes by a 49°C dip for 20 minutes
2. Vapor heat treatment: Fruit temperature is raised by saturated water vapor at 44.4°C until the center of the fruit reaches that temperature, and then held for 8.5 hours
3. Forced hot air treatment: 2 hours at 43°C + 2 hours at 45°C + 2 hours at 46.5°C + 2 hours at 49°C

## XI. DO’S AND DON’TS IN IPM

<table>
<thead>
<tr>
<th>S.No.</th>
<th>Do’s</th>
<th>Don’ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Deep ploughing is to be done on bright sunny days during the months of May and June. The field should be kept exposed to sun light at least for 2-3 weeks.</td>
<td>Do not plant or irrigate the field after ploughing, at least for 2-3 weeks, to allow desiccation of weed's bulbs and/or rhizomes of perennial weeds.</td>
</tr>
<tr>
<td>2.</td>
<td>Grow only recommended varieties.</td>
<td>Do not grow varieties not suitable for the season or region.</td>
</tr>
<tr>
<td>3.</td>
<td>Sow early in the season</td>
<td>Avoid late sowing as this may lead to reduced yields and incidence of pests</td>
</tr>
<tr>
<td>4.</td>
<td>Always treat the seeds/seedlings/planting material with approved chemicals/bio products for the control of seed borne diseases/pests.</td>
<td>Do not use seeds without seeds/seedlings/planting material treatment with biocides/chemicals.</td>
</tr>
<tr>
<td>5.</td>
<td>Adopt proper spacing in the field.</td>
<td>Do not damage the seedling while uprooting and transplanting.</td>
</tr>
<tr>
<td>6.</td>
<td>Maintain optimum and healthy crop stand which would be capable of competing with weeds at a critical stage of crop weed competition</td>
<td>Crops should not be exposed to moisture deficit stress at their critical growth stages.</td>
</tr>
<tr>
<td>7.</td>
<td>Use NPK fertilizers as per the soil test recommendation.</td>
<td>Avoid imbalanced use of fertilizers.</td>
</tr>
<tr>
<td>8.</td>
<td>Use micronutrient mixture after sowing based on soil test recommendations.</td>
<td>Do not apply any micronutrient mixture after sowing without soil test recommendations.</td>
</tr>
<tr>
<td>9.</td>
<td>Conduct AESA weekly in the morning preferably before 9 a.m. Take decision on management practice based on AESA and P: D ratio only.</td>
<td>Do not take any management decision without considering AESA and P: D ratio</td>
</tr>
<tr>
<td>10.</td>
<td>Install pheromone traps at appropriate period.</td>
<td>Do not store the pheromone lures at high temperature and preferably store in refrigerator. (5-10 °C)</td>
</tr>
<tr>
<td>11.</td>
<td>Release parasitoids only after noticing adult moth catches in the pheromone trap as per field observation</td>
<td>Do not apply chemical pesticides within seven days of release of parasitoids.</td>
</tr>
<tr>
<td>12.</td>
<td>Spray pesticides thoroughly to treat the undersurface of the leaves, particularly for whitefly, and other sucking pests harbouring the lower side of leaves.</td>
<td>Do not spray pesticides only on the upper surface of leaves.</td>
</tr>
<tr>
<td>13.</td>
<td>Apply short persistent pesticides to avoid pesticide residue in the soil and produce.</td>
<td>Do not apply pesticides during preceding 7 days before harvest.</td>
</tr>
<tr>
<td>14.</td>
<td>Follow the recommended procedure of trap crop technology.</td>
<td>Do not apply long persistent pesticides on trap crop, otherwise it may not attract the pests and natural enemies.</td>
</tr>
</tbody>
</table>
XII. BASIC PRECAUTIONS IN PESTICIDE USAGE

A. Purchase
1. Purchase only just required quantity e.g. 100, 250, 500, 1000 g/ml for single application in specified area.
2. **Do not** purchase leaking containers, loose, unsealed or torn bags; **Do not** purchase pesticides without proper/approved labels.
3. While purchasing insist for invoice/bill/cash memo.

B. Storage
1. Avoid storage of pesticides in house premises.
2. Keep only in original container with intact seal.
3. **Do not** transfer pesticides to other containers; **Do not** store exposed to sunlight or rain water; **Do not** store weedicides along with other pesticides.
4. Never keep them together with food or feed/fodder.
5. Keep away from reach of children and livestock.

C. Handling
1. Never carry/transport pesticides along with food materials.
2. Avoid carrying bulk pesticides (dust/granules) on head shoulders or on the back.

D. Precautions for preparing spray solution
1. Use clean water.
2. Always protect your nose, eyes, mouth, ears and hands.
3. Use hand gloves, face mask and cover your head with cap.
4. Use polythene bags as hand gloves, handkerchiefs or piece of clean cloth as mask and a cap or towel to cover the head (Do not use polythene bag contaminated with pesticides).
5. Read the label on the container before preparing spray solution.
6. Prepare the spray solution as per requirement.
7. **Do not** mix granules with water; **Do not** eat, drink, smoke or chew while preparing solution.
8. Concentrated pesticides must not fall on hands etc while opening sealed container. Do not smell pesticides.
9. Avoid spilling of pesticides while filling the sprayer tank.
10. The operator should protect his bare feet and hands with polythene bags.

E. Equipments
1. Select right kind of equipment.
2. **Do not** use leaky and defective equipments.
3. Select right kind of nozzles.
4. Don't blow/clean clogged nozzle with mouth. Use old tooth brush tied with the sprayer and clean with water.
5. **Do not** use same sprayer for weedicide and insecticide.

F. Precautions for applying pesticides
1. Apply only at recommended dose and dilution.
2. **Do not** apply on hot sunny day or strong windy condition; **Do not** apply just before the rains and after the rains; **Do not** apply against the windy direction.
3. Emulsifiable concentrate formulations should not be used for spraying with battery operated ULV sprayer.
4. Wash the sprayer and buckets etc with soap water after spraying.
5. Containers buckets etc used for mixing pesticides should not be used for domestic purpose.
6. Avoid entry of animals and workers in the field immediately after spraying.
7. Avoid tank mixing of different pesticides.

G. Disposal
1. Left over spray solution should not be drained in ponds or water lines etc. throw it in barren isolated area if possible.
2. The used/empty containers should be crushed with a stone/stick and buried deep into soil away from water source.
3. Never reuse empty pesticides container for any other purpose.
## XIII. PESTICIDE APPLICATION TECHNIQUES

Important Natural Enemies of Papaya Insect Pests

**Parasitoids**

- *Aphidius* spp.
- *Aphelinus* spp.
- *Encarsia formosa*
- *Eretmocerus* spp.
- *Anagrus flaveolus*
- *Stethynium triclavatum*

**Predators**

- Robber fly
- Red ant
- Ladybird beetle
- Spider
- Praying mantis
- Black drongo

**Plants Suitable for Ecological Engineering in Papaya Plantation**

- Alfalfa
- Sunflower
- Ocimum spp.
- Chrysanthemum spp.
- Spearmint
- Mustard
- Marigold
- Carrot
- French bean
- Cowpea
- Buckwheat
- Maize
